## Chapter 1

## Introduction

This study is a continuation of a series carried out by this author commissioned by the Australian Council of Deans of Science (ACDS) ${ }^{1}$. Another report on university science statistics between 2002 and 2009-2010 ${ }^{2}$ commissioned by the Office of the Chief Scientist, and again conducted by this author, also forms part of the series. The purpose of these reports is to identify and analyse trends in enrolments in science and technology in the Australian university system.
This study differs from these earlier studies in that it has been extended to cover all the so-called STEM areas of science, technology, engineering and mathematics. In the context of Australian higher education, the earlier studies covered only the Natural and Physical Sciences (which includes mathematics) from the national broad Field of Education classification, whereas the current study also includes analysis of three other broad Fields of Education: Information Technology, Engineering and Related Technologies, and Agriculture, Environmental and Related Studies.
Between them these studies have covered the period from 1989 to 2015, and they provide the opportunity to review the picture provided by the series as a whole. One would expect the data to provide a clear and unambiguous picture of the way that science enrolments have changed, and what influenced these changes, over this 26 -year period, in both broad terms and in detail. The source of data across the period covered in this report is the Commonwealth of Australia 'education department'. This entity has had many names over the years, and for simplicity's sake, it has been described as 'the Department' when being cited as a source. The format of the statistics used has been hard copy published and user-specified statistics, tables generated from data files made available by the Department, and more recently, from an online 'data cube’ system called uCube ${ }^{3}$.
However, this is not the case; several factors have had an impact on the exact coverage of higher education statistics. Over this period there have been

- structural changes such as the so called 'Melbourne model'
- ambiguity in the way that institutions report the statistics
- changes to the way in which the government collects these statistics
- modifications that it has made to the raw data
- changes to the form in which it releases the data.

These elements make direct interpretation of the data at times dubious and sometimes quite misleading.
It is the purpose of this chapter to provide the reader with an overview of these confounding influences, so that they can be readily identified when they occur in the data analysed in the body of this report, and they should be kept in mind when discussing these statistics generally.
Some influences are more easily discerned than others. For example, in 1989 the university student population increased from about 195,000 in the previous year to over 441,0000 . This seemingly

[^0]remarkable increase is simply the result of creating the 'unified national system' of universities from an antecedent binary system of universities and teaching-focussed colleges of advanced education ${ }^{4}$. Therefore, 1989 is when Australia's university sector was augmented by the numbers from the preDawkins colleges. In the 1988 Selected Higher Education Statistics, universities' and colleges of advanced education statistics were reported separately, something that was no longer necessary from 1989. ${ }^{5}$ By commencing the studies for the ACDS from 1989, this problem was avoided and justifiably focuses on science enrolments in the unified national system.

## The 'Melbourne Model'

Less obvious but no less confounding is the effect of the graduate school model adopted by the University of Melbourne, which was phased in from 2008, the so-called 'Melbourne Model', and the University of Western Australia from 2012. Table 1.1 demonstrates the impact on enrolment patterns for the University of Melbourne. It shows that between 2007 and 2015, nearly 3,000 more students were undertaking bachelor's degrees in the Natural and Physical Sciences ( +47 per cent), and in Agriculture, Environmental and Related Studies, the growth has been nearly 2,000 students ( +256 per cent).

Table 1.1 Enrolments: Students Enrolled in Bachelor's Degrees: University of Melbourne 2007 - 2015*

|  | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | Growth <br> No. | Growth <br> $\%$ |

Source: The Department. uCube.
The dramatic jump in BSc enrolments at the University of Melbourne from 2007 to 2008 is largely due to the transference of undergraduate engineering students into the BSc. In 2007 some 900 or so students commenced engineering degrees. From 2008 all such students enrolled in the BSc. National figures for BSc enrolments are significantly perturbed by this change, and by the counterpart change at The University of Western Australia from 2012.

National undergraduate enrolments in the Engineering and Related Technology Broad Field of Education are also significantly reduced by this change. Overall enrolments in this field, that include postgraduate studies, begin to pick up from 2011 when intending engineers begin to graduate from the BSc and enrol in the appropriate postgraduate engineering courses to obtain professional registration.

[^1]More remarkable, and of greater national impact, is the increase in enrolments in Agriculture, Environmental and Related Studies. Prior to 2008, intending architecture students would have enrolled in a bachelor's degree in the Architecture and Building Broad Field of Education. From 2008 onwards, it appears that many of the University of Melbourne's intending architects enrolled in the newly-created Bachelor of Environments, which was classified by the University as a course in the Agriculture, Environmental and Related Studies Broad Field of Education. This explains the phenomenal growth in Melbourne's contribution to national enrolments in the broad field of Agriculture, Environmental and Related Studies. Perhaps this problem will start to evaporate from 2017, because with respect to the training of future architects, the University announced some time ago that 'The Bachelor of Environments is not accepting applications for 2017 entry' ${ }^{\text {h }}$. The programmes to replace the Bachelor of Environments might be linked to a more appropriate Field of Education, one that better reflects the training of architects. Of course, the consistency of the time series has been disrupted forever.

The potential for policy misdirection will be clear from Table 2.1 (in the next chapter). It shows that the nation-wide pattern for Agriculture, Environmental and Related Studies was that it stayed pretty much the same size between 2002 and 2015. However, far from inferring a stable production of expertise in agriculture and environmental science, the increase at University of Melbourne by nearly 2,000 between 2007 and 2015 means that there must have been reciprocal declines elsewhere in the sector. The national aggregate figures mask a significant national shortfall.
An examination of the definitional criteria for the field of Agriculture, Environmental and Related Studies provides a strong argument that the inclusion of future architecture students constitutes a significant misclassification and, from the point of view of policy and transparency of data, a significantly damaging one. It is hard to see how the Bachelor of Environments degree meets the criterion that the '...main purpose of this Broad Field of Education is to develop an understanding of the management and use of natural resources, and the production of primary agricultural products ${ }^{7}$

A further indication of the impact of the Melbourne Model on the Agriculture, Environmental and Related Studies can be seen below in Table 4.9a. This table shows a remarkable increase in the amount of teaching to students in courses classified as Agriculture, Environmental and Related Studies in subjects in the Architecture and Building Broad Discipline Group from 66 EFTSL to 829 EFTSL (an increase from less than one per cent to just over nine per cent of all teaching to those students). Deeper analysis would show that nearly all of this remarkable change is related to practices at the University of Melbourne.

Table 1.2 shows analogous impacts from The University of Western Australia's adoption of a graduate school model. Most, perhaps all STEM undergraduate teaching has been moved into undergraduate courses in the Natural and Physical Sciences. Perhaps this also explains the decline in bachelor's degree enrolments in Health.

[^2]Table 1.2 Enrolments: Students Enrolled in Bachelor's Degrees: University of Western Australia 2011-2015*

|  | 2011 | 2012 | 2013 | 2014 | 2015 | Growth No. | $\begin{gathered} \text { Growth } \\ \% \end{gathered}$ |

Source: The Department. uCube.
The critical point is that graduate school-style models change the nature of the national enrolment time series for good. The 'Melbourne Model' has changed what university enrolments mean by dovetailing students into fewer undergraduate degrees, then having those students re-enrol in master's by coursework degrees in order to gain professional accreditation. It is therefore the case that since 2008, the number of undergraduate students in Natural and Physical Sciences programmes has increased, in a sense, 'artificially'. In addition, students who would have previously enrolled only in an undergraduate degree to gain professional standing in say, engineering or architecture, now have a subsequent postgraduate enrolment; as four-year professional undergraduate degrees have been replaced by a three-year BSc, followed by a two-year master's degree.

## Major changes to counting and classification

There have been two substantial shifts of definition in the data collection methodology relevant to the period 1989 - 2015. First, from 2001, separate Field of Study and Discipline Group classifications were replaced by a common classification of Fields of Education and Discipline Groups.
Second, until 2001 the number of students enrolled at Australian universities had been compiled according to a census methodology based on the number of students enrolled as at 31 March each year. In 2002 a revised methodology counted students enrolled at any stage of the year, rather than on a single date. That is, the 2002 enumeration methodology is based on counting every student enrolled at some time during the year, whereas the previous methodology was based on the count on a single annual census date. It could be argued that the post-2001 methodology is more accurate in one sense, but census date methodologies are more familiar, and easier to comprehend.

The change of methodology, by definition, increased the number of Natural and Physical Sciences students in 2001 by about seven per cent, from 62,000 to more than 66,000 . The impact on the other STEM fields of education was an increase of 19 per cent in Information Technology, nine per cent in Engineering and Related Technologies, and about ten per cent in Agriculture, Environmental and related studies.

It is important to appreciate that these two changes (of classification groups and counting methodology) mean that accurate and detailed longitudinal comparisons using hard copy published sources before 2002 are no longer an option.

## Modifications to the data

The 2002 change in enrolment enumeration artificially increased the number of people included in counts as 'students' compared with earlier years. In an apparent attempt to 'smooth' out the resulting discontinuity in enrolment time series the Department arbitrarily changed its on-line uCube statistics for 2001 to make these figures consistent with years 2002 and onwards. The uCube system now reports a total of 842,183 students in 2001, whereas the hard-copy published statistics for 2001 show that Australian higher education institutions had 726,418 students $^{8}$. (That is, there is a difference of about 16 per cent in the original 'official' published figure for 2001, compared with the 'new official' published figure for 2001).

For the sake of transparency, the Department's statistics should acknowledge that the 2001 figure now provided is an estimate of what might have been reported under the post 2002 enumeration methodology. In fact, the Department seems to have suppressed the 2001-2 figures by publishing statistical tables on line only from 2004, and the two sets of higher education time series on the Department's website run from 1949 to 2000, and 2003 to 2008, omitting years 2001 and $2002^{9}$.

## Changes to the way statistics are reported.

Higher education statistics are compiled by the Department's staff from data files supplied by universities. Until 2011, the Department's staff compiled aggregated data sets which were available to staff and researchers from universities and others, to download from their Departmental website. These data sets enabled a wide range of analyses on universities and their students to be undertaken.
Unfortunately, this system has been abandoned, and replaced with an on-line 'data cube' system, which though excellent in its own right, does not permit statistical analysis to the same level of detail. It would seem that there had been concerns about privacy. In addition, the Department's staff continue to publish a large number of summary tables at a range of levels of detail ${ }^{10}$. More detailed tables can be purchased for a time-based fee.

The higher education system's data integrity relies on universities adhering strictly to the definitions. These are contained in on-line data element dictionaries and glossaries that assist university staff in understanding the scope of what has to be collected. Data elements defined for the student collection include matters relating to the students themselves, such as their sex, date of birth, permanent and semester residence information (collected in the form of postcodes or overseas country codes), and background information on students' country of birth, year of arrival in Australia, language spoken at home, and Indigenous status. The student-sourced information is provided to universities at the time of enrolment. Another set of information on students is generated by universities: students' basis of admission, attendance mode (internal or external or a mixture of the two), attendance type (fulltime or part-time), and their liability for, or exemption from, paying fees of various types.

Still more information is provided by universities about the level, duration and name of the courses they offer, and the subjects taught in those courses ${ }^{11}$, and the characteristics of the teaching departments

[^3]which teach those subjects. Since 2001, universities have coded the courses they offered so they can be aggregated into fields of education. Quoting from the Department's documentation,

> The field of education classification is used to describe the principal subject matter of higher education and VET courses and units of study. This is also referred to as the Australian Standard Classification of Education (ASCED). Its main purpose is to ensure courses, specialisations and units of study with the same or similar vocational emphasis are reliably classified as belonging to the same "field of education". It is used nationally in all administrative and survey collections which incorporate data on education by field. ${ }^{12}$.

The subjects that students study within those courses can similarly be coded into 'discipline groups', an identical classification to the field of education classification.

The situation before 2001 for classifying courses and subjects has been written up in earlier studies. ${ }^{13}$
The current Field of Education classification is divided into 12 broad fields of education and subdivided into 83 narrow fields of education and 439 detailed fields of education. These are expressed with a two-, four- and six-digit code, respectively. Despite this wealth of diversity, the field of education classification is not necessarily of much value at levels of detail beneath the Broad Field of Education (the two-digit level), particularly in bachelor's degrees.

Within the Natural and Physical Sciences, there are 37 six-digit detailed fields of education to which universities could classify the science courses in which their students were enrolled, yet about half of 'science' students are enrolled in generalist degrees. The point of this is to show that the mere existence of a classification containing 37 detailed options does not provide real detail of enrolments. Of course, some students ARE reported as being enrolled in more specifically-described courses. These include courses in fields such as medical science, forensic science, food science, and laboratory technology, but the great majority of 'BSc' students have been reported as being enrolled in a generalist degree. Students, particularly those in bachelor's degrees typically enrol in a degree that can only be classified in a general manner. Students enrolled in generalist BSc degrees, for example, might eventually specialise in one or two science majors, but no matter how detailed the field of education classification is, the BSc course can usually be described only in a very general way. First year students often will not know whether they will eventually major in mathematics, chemistry or biology (for example). It is likely, therefore, that the BSc course will be classified by universities in some very 'general' way.

For these reasons, it is necessary to be wary when comparing patterns at different universities, or when comparing trends in Australia with trends in other countries. For instance, statements comparing Australia's university enrolment or graduation patterns compared with other nations need to be taken with a grain of salt, pending knowledge of what is being compared, and what information was supplied by either Australian, or overseas national counting houses. The main point is that although it is useful to aggregate courses according to their content, simply having a highlydetailed classification does not ensure comparability between universities unless identical coding practices are observed by all those universities. Many university courses, particularly at the undergraduate level, are generalist degrees.

[^4]Programmes of study that do not lead to a formal degree, diploma or certificate, but which comprise subjects that are part of an award course, are described as non-award courses.

The terminology used in the Field of Education classification is identical to the Discipline Group classification, but the distinction between the two is that 'fields of education' refers to enrolments of students in courses, and 'discipline groups' refers to enrolments in subjects the students study in their courses. Figure 1.1 provides a list of broad fields of education / discipline groups, and Appendix 2 is a list of the field of education / discipline group classification, down to the detailed level for the areas covered in this study.

## University statistics: yesterday and today

In some respects, Australian higher education statistics are among the best available in the world, even if they are not as good in 2018 as they had been in 2010. The system documentation provides universities with clear guidelines for universities to follow. Data validation computer programmes ensure that inconsistent reporting is kept to a minimum, but some universities, for example, report graduate numbers in more detail than others. Some universities report bachelor's degree civil engineering graduates as ' 0309 Civil Engineering' whereas others will report all graduates (irrespective of the narrow field of education) as ' 0300 Engineering and Related Technologies - General', or even '0399 Engineering and Related Technologies nec' ('not elsewhere classified'). In these circumstances, an accurate answer to a question about how many graduates qualified in civil engineering in 20XX can be problematic. Chapter 5 has a detailed analysis of STEM course completions.
Areas of shortcomings and inconsistencies in the detailed application of statistical variables in statistical collections of student data are mentioned elsewhere in this study. Now that people outside the Department no longer have access to data files, it is not possible to check on the consistency of universities' data.

Another consequence of this privacy issue is that in effect, there can now be more than one 'official' figure. Once the figures available via the Department's on-line uCube system are broken down into more detail, there can be minor differences in the figures. The following statement appears in the 'notes' section of uCube:

The data cube does allow customised tables to be produced with cells containing very small counts. To avoid any risk of disseminating identifiable data, a disclosure control technique called input perturbation has been applied to the data, with the exception of grand totals, whereby small random adjustments are made to cell counts. These adjustments (otherwise known as noise) allow for a greater amount of detailed data to be released and, as such, do not significantly impair the utility of the tabular data for use in broad level analysis. However, the relative impact of perturbation is larger for small cell counts, which therefore should be used with caution. Where unperturbed figures are required, users should consult the Higher Education Statistics published on the department's website

Private correspondence with the Department also advised that 'Historically there have been some quite large differences between uCube numbers and other published numbers'.

At time of preparation, information for years 2001 to 2015 was available via the aforementioned cross-tabulation program called uCube. Data for 2016 were added to uCube late in 2017. Information in more detail than the 'normal' published data for years 2002 - 2015 was purchased from the Department. The system is that purchasers specify the rows and columns they want in a table. As with the Department's published tables, low-count cells are indicted as ' $<5$ ', and other cells in rows and columns are 'not published' ('np'), so that it is not possible to work out the individual cell values by difference from row or column totals. An unfortunate aspect of this 'system', is that there are a couple of fields of education containing sub-degree courses that are scarcely of university-level status taught by few institutions. It is in these fields ('Food, Hospitality and Personal Services', and 'Mixed Fields') that low cell counts are most likely. Unfortunately, it is often the case that a 'np' cell is one that is of specific interest. However, there are ways around these pseudo-privacy inanities, and one can usually work out the values of the cells in which one is interested. Of course, one way to obviate the problem is to order tables that exclude the low-count fields of education. Other published data sources allow for such rows of data to be added back later, if one so wishes.

The source of all the tables produced for this study is identified below each table. The three options all emanate from the Department; they are uCube (the Department's on-line data cube system), published tables, available from the Department's website, and special tables purchased from the Department.

The next chapter presents overall background data to provide a context for the more detailed analysis in Chapters 3, 4 and 5.

## Chapter 2

## The sector 2002 - 2015: A summary of nation-wide patterns in learning, teaching and course completions

This chapter is concerned with overall developments (statistically speaking) since the configuration of the sector in its current form from 2002. Looking at the sector in this way provides a contextual starting point for a more detailed examination of the STEM fields and disciplines - science, technology, engineering and mathematics. This chapter examines data for all students, enrolled in courses at all levels, considering a range of variables. The tables produced here have been derived from the Department's web-based uCube 'drag and drop' table builder, from hard-copy or standard tables published by the Department, or from tables purchased from the Department's university statistics section. It should be noted that many of the tables produced via uCube or purchased from the Department do not 'add up' in their raw form, because some students are enrolled more than one course. In other words, a student enrolled simultaneously in a BSc and an engineering degree will produce an enrolment in each of the rows for Natural and Physical Sciences and Engineering but will appear in the year total only once.

The units of measurement in this chapter are first, student enrolments in courses, followed by an analysis of the teaching and learning of science by analysing 'student load', and finishing with a brief examination of course completions since 2002. Definitionally-speaking, and paraphrasing text from the Department's website, a student is 'enrolled' if he or she has been admitted to a programme offered by a higher education provider at the census date, or if that person is still entitled to continue with their studies and has not formally indicated before the census date that they have withdrawn from or deferred their studies ${ }^{14}$.

The term 'university' has been used throughout this document, but in fact, not all the students shown in these tables are enrolled at universities. Included in more than 1.4 million higher education enrolments for 2015 are 98,706 students enrolled in courses offered predominantly by private higher education providers. Within this total, nearly half were enrolled in private institutions in New South Wales, and about one-quarter in Victoria. These institutions are a $21^{\text {st }}$ century phenomenon, and growth has been spectacular. In 2002, enrolments courses offered by private institutions totalled just 375 students.

## Sector-wide enrolments

The principal focus of this study is the STEM fields, so it would seem appropriate to start with a table that follows changes in enrolments in these Broad Fields of Education between 2002 and 2015. Later chapters follow up with a more detailed examination of what has happened this century in the STEM Fields of Education and Discipline Groups.

Table 2.1 shows enrolments in courses offered by Australian universities and other 'higher education providers' for selected years in the period 2002 to 2015, by Broad Field of Education. Given this study's focus on the STEM areas, the STEM-predominant Fields of Education have been emphasised. In full, with the abbreviated descriptions (as used in most tables) in brackets, these are

[^5]01 Natural and Physical Sciences (N\&P Sciences) (which includes Mathematics)
02 Information Technology (IT)
03 Engineering and Related Technologies (Engineering) and
05 Agriculture, Environmental and Related Studies (Agriculture).
It should be remembered that because students can be enrolled in more than one course (e.g., BSc / LLB) the number of enrolments in any table built up from enrolments by Field of Education will exceed the number of students. For example, data for 2015 shown in Table 2.1 indicate that 72,857 of the $1,410,133$ students enrolled, were enrolled in more than one course.

Table 2.1 shows that enrolments in courses in these four fields of education increased by 32 per cent, against a sector wide growth rate in course enrolments of 56 per cent. Growth, however, has been restricted to Natural and Physical Sciences and Engineering, that grew by 67 per cent and 73 per cent, respectively. Information Technology declined by 23 per cent, and Information Technology's proportion of all enrolments has declined from seven per cent in 2002, to three per cent in 2015 . The proportion made up by student enrolments in courses in Agriculture, Environmental and Related Studies was unchanged over the period. In fact, there has been something of a recovery since a decline in numbers in the early years of the century. However, in a sense, this recovery is illusory, because much of the increase has been occasioned by revised enrolment patterns at the University of Melbourne (see explanation in Chapter 1). Within total STEM enrolments, the proportion made up by Agriculture, Environmental and Related Studies declined from eight to six per cent between 2002 and 2015. Other universities also produced increases in the number of enrolments in Agriculture (e.g., Charles Sturt University +264 ; UNE +336 ; Newcastle +259 ), but there were large decreases at several universities, including the University of Queensland -920; Sydney -543; Curtin -423 and Western Sydney -413. These figures were produced from uCube, but are not shown in the tables here.

Outside the STEM fields, the largest Fields of Education are Management and Commerce, Society and Culture, followed by Health. Of these three, Health has shown the strongest upward trajectory, with its enrolments increasing from eight per cent to 12 per cent between 2002 and 2015.

Figure 2.1 provides a visual representation of this, with Health added. From a system-wide perspective, Health appears to have grown relatively at the expense of the STEM fields. As shown in Table 2.1, STEM, Health and other Fields of Education have all expanded numerically, but the proportion of university enrolments in STEM have declined relative to all Fields of Education.

Table 2.2 and Figure 2.2 show course enrolments by all students according to course level. As shown in the previous table, the overall student population increased by 57 per cent between 2002 and 2015 and undergraduate enrolments continue to be the majority course level, representing about 70 per cent of all students in 2002, but declining relatively. Bachelor's degree numbers increased by nearly 305,000 or 49 per cent between 2002 and 2015. Australian higher education will likely reach 1,000,000 undergraduates within a year or so (more than 979,000 in 2015), with more than 65 per cent of these being enrolled in bachelor's degrees. Non-bachelor's undergraduate programmes have increased from about two per cent in 2002 to four per cent in 2015. The rate of growth ( 200 per cent) has been spectacular, but off a small base. Enabling courses increased their numbers of enrolments, but fewer students were enrolled in Non-Award students in 2015 compared with 2002.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

After bachelor's degrees, 'other postgraduate' enrolments represent the largest bloc of enrolments. The courses in this category include doctorates by coursework, postgraduate diplomas, master's degrees by coursework and graduate certificates. Enrolments in these programmes have increased from 20 per cent of all university enrolments in 2002 to 23 per cent in 2015 . They grew in number by 76 per cent over the period. It can be seen from Table 2.2 and Figure 2.2, that bachelor's degrees and other postgraduate enrolments are the main drivers of enrolment growth, representing over 90 per cent of all enrolments. These will be examined in more detail in Chapter 3.

Higher degree by research enrolments (that is, enrolments in master's degrees by research programmes or $\mathrm{PhDs})$ increased by over $21,000(+68$ per cent) over the period, but master's by research enrolments declined by over 1,600 (-16 per cent). The proportion of total enrolments represented by each level changed little over the period. From Table 2.2 it can be seen that higher degrees by research represented about five per cent throughout the period in question. The PhD is an important qualification, because it represents a barrier to entry to many professions, not the least, the academic profession and much of 'science'. It is no longer possible to separate PhD from master's degrees enrolments from statistics available via uCube, but the PhD has been subjected to closer scrutiny in Chapter 3 using purchased tables.

There was also strong growth in enabling courses $(+16,810 ;+237$ per cent $)$.
Figure 2.2 Enrolments: All Students by Course Level 2002-2015

Note: M x R refers to master's by research enrolments, but the numbers are so low as to be almost invisible in this graph.

Table 2.3 is a composite table that summarises the system-wide, all course levels situation that shows course enrolments by all students according to gender, citizenship status, attendance type, attendance mode and Indigenous status. Figure 2.3 shows the changes over time in the proportion of women, overseas students, undergraduates, full-time, internal and Indigenous students.
The proportion of women at Australian universities continues to rise. Since 2002, women's proportion of all enrolments has increased from 54 per cent to 55 per cent. The number of women grew by 60 per cent (to over 780,000 in 2015), compared with 54 per cent growth (to 629,693 ) in the number of men. Women first became the majority gender at Australian universities in $1987{ }^{15}$.

By 2015, the number of international students exceeded 363,000 , having grown by 96 per cent since 2002. Over that period, the proportion of overseas students increased from 21 per cent to 26 per cent. One of the main drivers of the trends in higher education enrolments this century has been the increasing number of enrolments by international students. Figure 2.4 enables this to be plainly seen, although expansion was more rapid in the early years of the period under examination. However, this expansion has not been consistent across the Fields of Education, a matter which will be explored in more depth in Chapter 3.

The proportion of students attending university full time has increased over the course of this century, increasing from 64 per cent to 71 per cent. The number of full time enrolments increased by 74 per cent, from 574,374 to over $1,000,000$.

\# Excludes 106 students for whom there was no information in 2015.
§ Domestic Enrolments; excl. Overseas Students

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

More students are enrolling in off-campus or multi-modal programmes than in the past. The proportion of internal (on-campus) enrolments increased by 46 per cent between 2002 and 2015, but the proportion of internally enrolled students declined from 80 per cent to 74 per cent over the period. The number of external students increased by 76,614 , or 56 per cent, with multi-modal enrolments increasing spectacularly, by 108,877 , or 276 per cent, growing from four per cent of all enrolments in 2002 , to 11 per cent in 2015. A multi-modal enrolment is the situation when a unit of study is undertaken partially on an internal mode of attendance and partially on an external mode of attendance. The proportion of external enrolments was 15 per cent at both ends of the period considered here.

[^6]Indigenous student numbers increased by 82 per cent over the period, but numbers remain low. According to the Australian Bureau of Statistics, in 2011 there were just under 670,000 Indigenous Australians, or three per cent of the total population ${ }^{16}$. However, as a proportion of the university domestic student population, Indigenous students represent just over one per cent.

Figure 2.3 summarises the trends for the groups of students specified in Table 2.3.
Figure 2.3 Enrolments: Proportion of Students with Selected Characteristics: Internal, Undergraduate, Full-time, Female, Overseas and Indigenous Students 2002-2015

Table 2.4 presents the distribution of university enrolments by state / territory across the sector, over the period 2002 to 2015. A minor imprecision in this distribution is that some universities have enrolments off-shore or in states / territories other than their 'home' state, and the Multi-State institutions (comprising the Australian Catholic University and those non-university private institutions that have campuses in several cities in several states / territories) are spread across states and territories by definition. Perhaps there is a minor inconsistency in the way 'out-of-state' statistics are represented. For example, Central Queensland University students enrolled in campuses in Sydney and Melbourne show as Queensland enrolments. However, the enrolments of students at the Australian Catholic University are located in New South Wales, Victoria and the Australian Capital Territory, but are described officially as 'multi-state'.

There was strong growth in university enrolments in all states and territories. Victoria had over 152,000 additional enrolments in 2015 than in 2002, an increase of 67 per cent. The proportion of enrolments in Victoria increased by about two per cent over the period (from 25 per cent to 27 per cent), whereas the share of enrolments in New South Wales and Queensland dropped slightly. However, New South Wales remains the state with more university students than any other. In 2015, New South Wales and Victoria together had 58 per cent of the nation's university students.

§ \%: Distribution of Australian Population, by State. Source: ABS 3101.0 Australian Demographic Statistics September 2016 http:// www.abs.gov.au/ausstats/abs@.nsf/mf/3101.0

Column 2 of Table 2.4 also allows for a comparison of state and territory populations compared with their proportion of university students. On the basis of these gross figures, it would appear that university students in the states of Victoria and Western Australia and the ACT are slightly overrepresented, and slightly under-represented in New South Wales and South Australia.

Table 2.5 summarises university enrolments by university. Institutions with fewer than 10,000 enrolments and private providers have been wound into the 'Other Institutions' row. Monash University is the nation's largest in terms of the size of its student body, and in 2015, had about 10,000 more students than RMIT. Swinburne University of Technology and RMIT grew the most between 2002 and 2015, adding 22,787 (+159 per cent) and 21,833 (+57 per cent) students, respectively. Monash, the University of Melbourne, Deakin University, the University of Tasmania and the Australian Catholic University also grew by $18-19,000$. Only Central Queensland University shrank over the period, by 1,463 enrolments, or seven per cent. 'Other Institutions' demonstrated the most spectacular growth (of more than 102,000 ), due largely to creation and growth of private higher education in the 21st century.

Recent years have seen changes in the situation for some universities. For example, Monash's Gippsland Campus was transferred to Federation University Australia in 2014, and it is in the process of doing the same with its Berwick Campus. There have also been occasional rumblings about Deakin University and its campus in the regional city of Warrnambool, with suggestions in 2016 about closure of the campus ${ }^{17}$, with a later indication that this was not going to occur ${ }^{18}$.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

As noted earlier, one of the changes since the start of the 21 st century has been the establishment of private higher education institutions. Table 2.6 shows that there were nearly 99,000 students enrolled in these institutions in 2015, representing seven per cent of all enrolments. The incidence of enrolments
in the STEM fields is lower than the overall pattern, however, having risen to three per cent of all STEM enrolments by 2015 .

## Student load: teaching and learning

So far, student enrolments in courses have been considered. This section examines the subjects studied by students as part of the courses they are enrolled in. Whereas enrolments measure the number of individuals enrolled in a course, some of whom will be attending full-time and others parttime, student load is a measurement of the number of 'equivalent' full-time students, dubbed 'equivalent full-time student load' (EFTSL). A full year's work is designated as being 1.000 EFTSL. A student enrolled in four equally-sized subjects that represent a 'normal' year's work would therefore generate 1.000 EFTSL. If another student were to be enrolled in only two such subjects, they would generate 0.500 EFTSL. The concept is therefore important because not all students take a full-year's work in their studies. Therefore, the total student load will always be less than the total enrolments, the latter being a headcount. In 2015, the 1.4 million enrolments generated an equivalent full-time count of just over 1.0 EFTSL. This indicates, therefore that the 'average' student is about 71 per cent full time. Examining EFTSL also provides a metric for the amount of teaching being provided.

Subjects are classified into discipline groups. The nominal classification is the same as the field of education classification which is used to classify courses, but if the term 'discipline group' is used, it is referring to the subjects that students are enrolled in. Refer to Appendix 1 for a full listing of broad, narrow and detailed Fields of Education / Discipline Groups.

Looking at overall broad patterns of teaching, Table 2.7 summarises the distribution of student load by Broad Discipline Group. It shows that the amount of teaching non-STEM disciplines increased by 66 per cent over the period, compared with an increase of 44 per cent in STEM teaching. In the main, this difference exists because of the decline in Information Technology. The amount of Engineering teaching increased by 93 per cent, and in the Natural and Physical Sciences, the increase was 66 per cent. The teaching of Agriculture, Environmental and Related Studies, the smallest of the 'traditional' university disciplines is quite low, but it increased from 8,931 EFTSL to nearly 13,000 EFTSL over the period.

Among other disciplines, growth was the most spectacular in Health, which increased by 142 per cent, or 81,473 EFTSL. This means that in 2015, subjects in the Health disciplines were being taught to more than 81,000 more equivalent full-time students in 2015 compared with the situation in 2002. The next-largest discipline in terms of growth was Management and Commerce $(+78,244$ EFTSL, or +68 per cent), followed by Society and Culture ( $+69,369$ EFTSL, or +41 per cent).

Figure 2.4 compares teaching in STEM and non-STEM disciplines, abd shows the proportion ot total teaching made up by STEM subjects.

Figure 2.4 Student Load: EFTSL in STEM and non-STEM Disciplines, and STEM \% of Total - 2002-2015

Table 2.8 examines the distribution of student load by level of course. In parallel with patterns relating to enrolments, there has been quite strong growth across most levels of course, with teaching in bachelor's degrees, the most numerous course level, increasing by 47 per cent between 2002 and 2015. Strong growth was also the case in courses at the other postgraduate level.

Looking at growth in student load by gender (Table 2.9), proportions and growth stayed the same across the period. The male to female ratio has been about $45: 55$ since 2002, and there has been growth of about 60 per cent in enrolments by both men and women. This figure is in contrast with the growth patterns in course enrolments: the number of male students increased by 54 per cent, compared with growth of 60 per cent among female students. Among the possible reasons for this is that male students are perhaps more likely to be enrolled full-time. For example, in 2015, 73 per cent of male students were enrolled full-time, compared with 69 per cent of female students (calculated from uCube).

Comparing domestic with overseas students' student load (also Table 2.9), the proportion of total EFTSL in teaching domestic students decreased from 80 per cent to 73 per cent of the total. The growth in student load taught to overseas students increased by 111 per cent, cf. 47 per cent to domestic students.

Finally, in this summary of student load, Table 2.10 presents a distribution of the 'liability status' of students, that is how students pay for, or are supported, in their university studies. Commonwealth Supported Students (i.e., domestic, subsidised students, paying HECS / HELP) are the largest group, representing 61 per cent of the total in 2015 (down from 68 per cent in 2002), but the number of these increased by over 181,000 EFTSL over the period. The next largest group covers overseas students, with an increase of nearly 143,000 EFTSL, or 111 per cent. The number of fee-paying domestic students more than doubled between 2002 and 2015.

## Course completions: higher education outputs 2002-2015

A successfully obtained qualification is the usual goal of university study, and Table 2.11 summarises sector-wide course completions by Broad Field of Education between 2002 and 2015. The table shows that the number of qualifications awarded increased by 62 per cent, from over 206,000 to nearly 335,000 . Because some students have enrolled in more than one course, the number of courses completed therefore exceeds the number of people, as was the case with enrolments counts involving the Field of Education classification. In 2002, 5,771 persons were granted two awards, and by 2015, this number had risen to 9,760 . Course completions are a lagging indicator, but the growth in completions is a function of the growth in enrolments.

Looking at the progress of awards in STEM Fields of Education, the rate of growth between 2002 and 2015 was 31 per cent, compared with growth in all Fields of Education of 62 per cent. However, there was strong growth in Engineering ( $+9,217$, or +85 per cent) and in Science ( $+10,061$, or +72 per cent). There were 5,001 fewer awards in Information Technology, and with completions in Agriculture (a relatively small field), there was a growth over the period of ten per cent, but there had been a decline in the number of students completing courses of three per cent. The proportion of STEM course completions declined from 23 per cent of all completions in 2002 to 19 per cent in 2015. In the intervening year 2012, the proportion got to as low as 17 per cent.

FoE = Broad Field of Education

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Among other broad Fields of Education, the big movers in course completions were Health $(+26,006$, or 109 per cent) and Management and Commerce $(+42,456$, or 74 per cent).

Figure 2.5 summarises the situation with course completions since 2002, comparing STEM and nonSTEM Fields of Education. The modest increase in STEM course completions is clear (left axis), as is the declining proportion of all completions represented by STEM graduates (right axis). However, there has been growth in the past few years in the number of course completers in Engineering and the Natural and Physical Sciences, with more modest growth in Agriculture, Environmental and related Studies, and the decline in the number of completions in Information Technology.

Figure 2.5 Course Completions: STEM and non-STEM Compared 2002-2015

Looking at course completions by level of course (Table 2.12), the largest growth occurred in bachelor's degrees ( $+53,229 ;+42$ per cent), followed by other postgraduate completions ( $+50,907$; +81 per cent). Completions of bachelor's degrees declined from 63 per cent of the total, to 55 per cent between 2002 and 2015. At the same time non-research postgraduate award numbers increased from 34 per cent to 38 per cent of the total. Postgraduate by research completions increased by 71 per cent, but their proportion of all completion stayed at three per cent across the period examined.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Figure 2.6 provides a summary graph of the number of course completions between 2002 and 2015 (plotted against the left axis, and the proportion of these completions by course level on the right. Annual completions increased from about 200,000 per year in 2002 to over 325,000 per year by 2015. The lines on the graph indicate a decline in the proportion of the total made up by undergraduate completions and the reciprocal increase in the proportion of completions in courses at the other postgraduate level. It can be seen that as the overall number of course completions increased each year, the proportion of undergraduate qualifications awarded each year was declining slightly, as the number of Other Postgraduate awards was increasing. The proportion of higher degrees by research was about the same across the period.

Figure 2.6 Course Completions: All Students in All Course Levels - 2002-2015

Table 2.13 examines the distribution of system-wide course completions by gender and citizenship status. Women represented 57 per cent of all course completions in 2015, up from 55 per cent in 2002. The number of female completers increased by 66 per cent $(+73,340)$ compared with a 57 per cent increase among men $(+50,572)$.

As was the case with enrolment trends, there has been strong growth in the number of overseas students completing university qualifications. The number of international completions more than doubled between 2002 and 2015, and the rate of increase far outstripped that for domestic students. The international proportion of course completions increased from 25 per cent in 2002, to 33 per cent in 2015. It should be noted, however, that in 2009 , the proportion of all course completions made up by overseas students was nearly 36 per cent.
Table 2.14 shows the number of course completions by university within state / territory. In 2015, the 'Top 10' universities in terms of their numbers of course completers (ranked) were Melbourne, Monash, RMIT, Sydney, the University of Queensland, Queensland University of Technology, Curtin, Griffith, Deakin and University of Technology Sydney. It should also be noted that taken together, the non-university institutions produced around 26,367 course completers in 2015, and this would rank them at the top if this group is taken to be a single entity. In terms of growth between 2002 and 2015, RMIT, Melbourne, Sydney and Griffith each increased their 'output' by more than 4,000 .

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

The institutions described as 'non-university' are mainly small private providers.
The next three chapters provide more detailed information on the students enrolled in programmes in the STEM Fields of Education, with Chapter 3 focussing on student enrolments Chapter 4 provides an in-depth examination of Student load (EFTSL), looking both at the patterns of teaching of the STEM disciplines, and the students to which that teaching has been provided. In doing so, it is possible to see how the composition of the degrees in the STEM Broad Fields of Education has changed. Chapter 5 looks at STEM course completions in considerable detail, including PhDs in the Natural and Physical Sciences.

## Chapter 3

## STEM Enrolments: Ups and downs in the 21st century

The main purpose of this chapter is to present the results of a closer examination of STEM enrolments since 2002. The Deans of Science were also interested in hearing about what has been happening in terms of the production of future medical practitioners, but such questions are less easy to answer, because medical practitioner training is buried within the 'Health' broad Field of Education, along with other types of 'medicine'. Nonetheless, some information for examining this group of students has been provided in tables towards the end of this chapter.
As shown in Table 3.1, the number of STEM enrolments increased by nearly 73,000 , an increase of 32 per cent. These figures need to be compared with the growth of over 464,000 , or 66 per cent, in non-STEM fields of education. Non-Award course enrolments declined over the period, but these represented only one or two per cent of all enrolments. However, growth in STEM enrolments has been slower than in non-STEM fields, declining from 24 per cent to 20 per cent of the total.
Looking at the STEM fields individually, Table 3.1 reveals the changes that have occurred, and Figure 3.1 is a graph of the enrolments in each of the four STEM fields between 2002 until 2015. Enrolments in programmes in the Natural and Physical Sciences have been reasonably steady, and increased by 67 per cent over the period, more than 46,000 . In 2015, enrolments in the Natural and Physical Sciences increased from being 30 per cent of STEM enrolments, to 38 per cent.

Enrolments in Information Technology have also recovered somewhat since the steady decline from the situation (the peak) in 2002. In the period 2002 to 2015, Enrolments in Information Technology dropped from over 79,000 in 2002, to around 50,000 in the years 2007-2012, but by 2015, they had risen again to over 60,000. Information Technology enrolments have declined by 23 per cent, but the decline from 2002 to 2007 was nearly 37 per cent. There were more enrolments in Information Technology courses in 2002 than in the other STEM fields, but enrolment losses have changed this situation. The relative decline in the place of Information Technology within the STEM fields has been considerable: in 2002, Information Technology enrolments represented 35 per cent of all STEM enrolments, but in 2015, the proportion had declined to 20 per cent.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Figure 3.1 Enrolments by Broad Field of Education: STEM Fields 2002-2015

Engineering and Related Technologies enrolments have grown more than other the STEM fields, increasing by over 45,000 , or 73 per cent between 2002 and 2015. It increased its relative presence from 27 per cent to 35 per cent.

As an extension to Table 3.1, Table 3.2 demonstrates what has happened in enrolment patterns within the STEM fields of education by re-basing the distribution according to STEM enrolments rather than enrolments in all fields of education. The Natural and Physical Sciences increased their relative presence from 30 per cent to 38 per cent between 2002 and 2015. At the same time, enrolments in Engineering and Related Technologies courses increased from 27 per cent to 35 per cent. Information Technology enrolments, the largest group within STEM in 2002 declined from 35 per cent to 20 per cent of STEM enrolments. Enrolments in Agriculture, Environmental and Related Technologies courses declined in the early part of the 2000s but recovered by 2015 to be at about the same level as they had been in 2002. The proportion of these enrolments of all STEM enrolments declined from about eight per cent to six per cent. However, comments in Chapter 1 concerning the consistency of the statistical time series should be borne in mind.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

## Male and female students

Looking at STEM and non-STEM enrolment patterns by gender, it can be seen from Table 3.3 that women have a strong majority overall, comprising about 55 per cent of all enrolments in 2015. However, the female presence in STEM programmes was a relatively modest 32 per cent, whereas they made up 61 per cent of the enrolments in the non-STEM fields. The proportions involved did not really change between 2002 and 2015, but the number of women in STEM programmes increased by 21,755 or 29 per cent. It should also be noted that although women make up 32 per cent of all STEM enrolments, they make up around half of enrolments in Agriculture and Natural and Physical Sciences,
but only 17 and 19 per cent of Engineering and Information Technology enrolments, respectively. These fields of education continue to be the ones to which women are least attracted. The female proportion of enrolments in Engineering has scarcely increased this century, even if the proportion had been much lower in the past. The proportion has gone backwards in Information Technology. Expansion in STEM enrolments, then, was predominantly male, with an extra 50,995 students between 2002 and 2015. However, the number of women in STEM increased by nearly 22,000, including an extra 8,024 in Engineering. The proportion of women undertaking STEM programmes is clearly much lower than their proportion of non-STEM programmes.

\# Excl. 106 students for whom there was no information on gender in 2015.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Of course, another aspect of the uptake of STEM programmes is that within the main growth area, that is, overseas students, the proportion of women is lower. Figure 3.3 provides a visual comparison. The solid columns represent domestic female students in STEM and non-STEM fields of education, and the patterned bars represent overseas female students. Even though the proportion of female domestic students in STEM is relatively low (being about 32 per cent, as opposed to about 61 per cent in non-STEM courses).

Figure 3.2 Proportion of Female Students Enrolled in Courses in STEM and non-STEM Fields of Education

## Domestic and overseas students

A major driver of growth in Australian higher education has been derived from expansion in the numbers of overseas students, nearly all of whom pay full-cost tuition fees. Table 3.4 considers all students enrolled in all levels of course, according to whether they are domestic or overseas students. As noted earlier, the great majority of university students are enrolled in bachelor's degrees or other postgraduate programmes. As was shown in Table 2.2, these degrees had enrolments of more than 928,000 and 321,000 , respectively, representing about 89 per cent of all enrolments. Because of the relative size of these two levels of course, they will be subjected to more detailed analysis later. Doctoral education is also important, so that will also be looked at, even though the numbers are much smaller.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

From Table 3.4 it can be calculated that domestic student numbers increased by 47 per cent and overseas student numbers increased by 96 per cent between 2002 and 2015 (see also Table 2.3). Overseas students therefore increased from about 21 to 26 per cent of the total. This growth was greater in the STEM fields (in which fields of education the proportion increased from 24 to 30 per cent of all STEM enrolments). In non-STEM fields, the proportion of overseas student enrolments increased from 18 to 23 per cent. However, changes within the STEM fields varied between fields. In 2015, Overseas students represented 16 per cent of students in the Natural and Physical Sciences field, 22 per cent of those in the Agriculture, Environmental and Related Studies field, 36 per cent in Engineering and Related Technologies and 49 per cent in Information Technology. In 2002, the equivalent proportions had been ten per cent, six per cent, 22 per cent and 41 per cent, respectively. In Information Technology, even though the proportion of overseas students increased, the overall number did not, because of the progressive decline in enrolments in that field of education. Overseas students have a relatively lower presence in the non-STEM fields of education, but their numbers increased from just under 125,000 to over 263,000 , an increase of 111 per cent. Domestic students in non-STEM fields rose by around 326,000 , or 56 per cent. The pattern of presence of overseas students in STEM, therefore is based predominantly on the attractiveness of information technology and engineering, rather than interest in agriculture or general science.

The contents of Table 3.4 are re-presented in Figures 3.3 and 3.4, for domestic students and overseas students, respectively. The columns represent enrolments in the individual STEM fields and all nonSTEM fields, to be measured against the left axis. The dotted lines, to be measured against the right axis, represent the percentage of overall STEM enrolments and non-STEM enrolments.

The situation for domestic students made clear by the graph is that a much higher proportion of nonSTEM students are domestic: around 80 per cent. This contrasts with the STEM situation, where the proportion of domestic students is around 20 per cent.

Figure 3.3 All Domestic Students: STEM Fields of Education and Non-STEM Fields 2002-2015

For overseas students, the pattern is different. The proportion of students in both STEM and nonSTEM fields alike is about 20 per cent. Almost half of all overseas students were enrolled in Management and Commerce courses in 2015.

Figure 3.4 All Overseas Students: STEM Fields of Education and Non-STEM Fields 2002-2015

Looking more closely at individual universities, Table 3.5 shows enrolments divided into STEM and Other than STEM courses, ranked by the numerical increase in STEM enrolments. The most growth in enrolments in STEM courses occurred at the University of Melbourne, but five universities increased by more than 5,000 enrolments (plus the catch-all 'Other Institutions': an amalgam of smaller universities and private providers).

Table 3.5 Enrolments: All Students by Institution by STEM and Other than STEM Fields of Education: 2002 and 2015* (Ranked according to extent of growth in STEM enrolments)

Source: The Department. uCube.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Table 3.6 demonstrates that one of the changes in the pattern of enrolments this century has been a form of 'bracket creep', from undergraduate to postgraduate. Although there was little change in the proportion of postgraduate by research enrolments, there was a considerable transfer between the undergraduate and non-research 'other' postgraduate categories. Within the STEM fields of education, the slippage between Undergraduate and Other Postgraduate was about ten per cent in Agriculture,

Environmental and Related Studies, and smaller amounts in the other STEM fields of education. In Agriculture, there was also a relative shift between Postgraduate by Research (PGR) and Other Postgraduate (OPG) programmes. There was also slippage in the non-STEM fields of education, but to less an extent than in the STEM fields. Undergraduate (UG) enrolments in non-STEM programmes declined from 73 per cent to 71 per cent of all enrolments between 2002 and 2015, compared with a decline from 79 per cent to 75 per cent in STEM undergraduate enrolments. It should be noted that undergraduate enrolments in the Natural and Physical Sciences remain high: 82 per cent in 2015, down from 84 per cent in 2002.

## Drilling down

The largest bloc of students is enrolled in bachelor's degrees, followed by other postgraduate (OPG) courses, and both of these deserve closer scrutiny. The PhD as the major research degree is also
important, particularly in STEM (and more particularly in the Natural and Physical Sciences). These have also been examined, even if the numbers are small compared with bachelor's and OPG numbers. The training of future medical practitioners is also of interest to deans of science, and there are few tables concerning this group

## Bachelor's degree enrolments

Table 2.2 (above, p. 12) showed that bachelor's degree enrolments declined from about 70 per cent to about 65 per cent. That table also showed that most of this relative decline came about as the result of increased enrolments in Other Postgraduate courses (which increased from 20 to 23 per cent of all enrolments).

Table 3.7 shows that the number of enrolments in bachelor's degree courses expanded from 675,254 to nearly one million, a rate of growth of over 48 per cent. By comparison, STEM enrolments increased by 23 per cent, and non-STEM enrolments by 57 per cent. Within STEM, Science enrolments increased by over 35,000 , ( +62 per cent), and Engineering by nearly 25,000 enrolments ( +52 per cent), but IT enrolments declined by more than 20,000 ( -35 per cent), and Agriculture stayed roughly the same between 2002 and 2015.

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Tables 3.8 and 3.9 consider patterns of enrolments by female and male students and domestic and overseas students, respectively. Women have been in the majority among university enrolments since the mid-1980s, and at the bachelor's degree level, their proportion has not changed over the course of the 21st Century.

As shown in Table 3.8, the number of women increased by nearly 170,000 over the period, compared to an increase of about 135,000 in the number of men. The patterns varied between STEM and nonSTEM, and also within STEM fields of education. The proportion of women in STEM at the bachelor's degree level stayed the same ( 33 per cent) between 2002 and 2015, due largely to the low presence of women in Engineering and IT ( 16 per cent in both cases in 2015). The proportion of women in IT declined from 24 per cent in 2002. Even in Science, the proportion of women declined, from 54 per cent to 50 per cent, but nonetheless, there were nearly 12,000 more female Science bachelor's degree students in 2015 compared with in 2002. The proportion of both women and men in STEM programmes declined over the period.

\# Excl. 66 students for whom there was no information on gender in 2015

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Table 3.9 shows that the proportion of overseas students in all bachelor's degrees increased from 17 per cent to 19 per cent during the period examined, having increased from about 111,000 to more than 180,000. Overseas students are more likely to be enrolled in STEM courses: in 2015, 24 per cent of overseas bachelor's degree students were enrolled in STEM courses, cf. 21 per cent of domestic students. The reciprocal students ( 76 per cent and 79 per cent) were enrolled in non-STEM programmes. However, the proportion of overseas students in STEM courses had been 32 per cent in 2002. Among Other Postgraduate enrolments, 23 per cent of overseas students were enrolled in STEM courses, compared with nine per cent of domestic students. There are distributional differences within STEM programmes. At the bachelor's degree level, patterns follow the overall pattern, with higher proportions of enrolments in Engineering and Information Technology. This is to be expected, because bachelor's degree enrolments represent 66 per cent of all university enrolments.

Table 3.9 Enrolments: Bachelor’s Degree Students by Citizen/Resident Status 2002 - 2015*

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Another way to examine enrolment trends is to look at the numbers of students commencing university studies. This is particularly relevant to bachelor's degrees, because they are the single largest courselevel bloc of university enrolments, and bachelor's degree students study for three or four years in order to complete most offerings at the bachelor's level. Table 3.10 shows enrolments by students commencing bachelor's degrees over the past few years. The rough pattern with commencing enrolments is that of the number that commence, some will 'drop out' or change university or course, and those that 'survive' the first year will continue for another two or more years until completing the course.

Table 3.10 Enrolments: Commencing Bachelor's Degree Students by Broad Field of Education. Numbers, Percentage \& Growth: 2002-2015*

| Broad Field of Education | 2002 | 2007 | 2012 | 2015 | Growth |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

* Refer to Chapter 1 for an explanation of factors that have disrupted aspects of the statistical time series

Table 3.10 shows overall growth in commencing bachelor's degree enrolments of 55 per cent, comprising 65 per cent growth in non-STEM courses, and 22 per cent in STEM courses. Within STEM courses, the well-documented decline in Information Technology enrolments is evident, with no change in Agriculture, Environmental and Related Studies, and growth in both Engineering and Related Technologies and Natural and Physical Sciences. However, these patterns need closer examination, in light of the introduction of a graduate school model at two universities. Although the rate of growth in Engineering and Related Technologies programmes has been quite strong, it has been lower than the sector-wide growth. However, a possible explanation for this is that by 2015, the University of Melbourne had 800 fewer commencing enrolments in Engineering, and nearly 500 fewer at the University of Western Australia ${ }^{19}$. If we assume that future engineers at these two universities enrol in a course such as BSc, it could indicate that up to 1,300 of the increase in Natural and Physical Sciences enrolments was effectively produced by the change in engineering arrangements at these two universities. If future medical practitioner enrolments also saw a transfer of students from 'medicine' within the Health Broad Field of Education to a science or bioscience degree within the Natural and Physical Sciences Broad Field of Education, it is possible that an additional 700 or so students per year have been added to the number commencing Natural and Physical Sciences courses at the bachelor's degree level.

According to Table 3.10, there was no growth in bachelor's degree commencements in Agriculture, Environmental and Related Studies. However, by producing a uCube table of the appropriate student population, it can be seen that bachelor's degree commencements in Architecture and Building courses declined from 545 in 2002 (and a peak of 602 in 2007) to zero since 2013. If many of these students had enrolled in Melbourne's Bachelor of Environments, classified as being a programme within the Agriculture, Environmental and Related Studies Broad Field of Education, then it indicates an overall decline in 'traditional' agriculture, forestry and environmental science enrolments elsewhere in the system. The point is that even though the time series suggests a steady-state situation, in reality, there has likely been a down turn in this Broad Field of Education.

## Other Postgraduate (OPG) enrolments

Enrolments in OPG course increased from over 182,000 in 2002, to over 323,000 in $2015(+140,545$; +77 per cent). This growth was greater in non-STEM fields of education, in which growth of 90 per cent was experienced. In comparison, STEM enrolments at this level increased by only 10 per cent.

[^9]The proportion of enrolments in STEM declined from 18 per cent in 2002, to 14 per cent in 201, with the greatest relative loss occurring in IT (from 11 per cent to six per cent). IT still produced more OPG enrolments than the other STEM fields of education, but the number declined by 1,797 over the period. Refer to Table 3.11.

Table 3.12 examines gender distributions in OPG courses. Whereas the proportion of women in all OPG courses increased from 49 per cent to 55 per cent, among STEM courses the increase was more or less the same over the period. The proportion of women was considerably higher in the relatively small Agriculture and Natural and Physical Sciences fields of education. Engineering and IT have much lower proportions of women, but the female presence is higher than in bachelor's degrees.

Table 3.13 summarises the relative presence of domestic and overseas students in OPG courses. Whereas about 19 per cent of the bachelor's degree students in 2015 were overseas students, among OPG courses, the proportion was 38 per cent. This proportion had increased from 33 per cent in 2002, indicating the strong attractiveness of programmes at this level, and particularly within the STEM fields of education. In fact, 61 per cent of enrolments in STEM OPG courses in 2015 were by overseas students, up from 47 per cent in 2002. In Engineering and IT, the proportions of overseas students were 60 per cent and 77 per cent, respectively.

## PhD Enrolments

The PhD degree has always been important in the STEM fields, particularly in 'science'. Many research jobs are STEM-related (and particularly science-related) and a PhD degree represents a barrier-to-entry for many careers in science. For this reason, it is important for the PhD to be considered as a discrete course level, despite the fact that PhDs make up only about four per cent of all enrolments.

Table 3.14 summarises enrolment patterns for PhDs between 2002 and 2015. PhD enrolments have represented about four per cent of all enrolments for the whole period since 2002, and during that time, the proportion of PhDs in STEM fields of education increased from 37 per cent to 44 per cent. The number of STEM enrolments at the PhD level nearly doubled, from 12,730 to 24,960. At the same time, enrolments in non-STEM fields increased by 51 per cent, to 32,170 by 2015 . Within STEM fields, enrolments in Science represented almost half in 2015, down from about 53 per cent in 2002. The strongest proportionate growth was demonstrated in Engineering, with an increase of 138 per cent over the period.

Table 3.15 examines the gender differences among PhD enrolments. In 2015, women made up 39 per cent of STEM PhD enrolments, compared with 59 per cent of PhD enrolments in non-STEM fields. However, the overall STEM result is held back by the lower proportions of women in Engineering and Information Technology ( 26 per cent and 27 per cent, respectively). It should be noted, however, that the percentage of women in PhDs in Engineering and Related Technologies and Information

Technology is greater than is the case for bachelor's degree students (see Table 3.2). In Agriculture and Natural and Physical Sciences, women made up nearly half of all PhD enrolments. Looking at growth between 2002 and 2015, 41 per cent of the expansion of enrolments in the STEM fields was by women, compared with 68 per cent in the non-STEM fields.

Table 3.16 shows the remarkable expansion in PhD enrolments by overseas students. In 2002, overseas students made up 17 per cent of STEM PhDs, and 15 per cent of enrolments in non-STEM fields. In 2015, the equivalent figures were 47 per cent and 24 per cent, respectively. Fifty-five per cent of all PhD enrolments in Engineering in 2015 were by overseas students, and in Information Technology, 53 per cent. Even in the Natural and Physical Sciences, the proportion was 41 per cent. The fact of this expansion presents an intriguing policy issue, because particularly in the STEM fields, nearly half of this future intellectual elite are from overseas. Considerable resources need to go into providing this doctoral training, and a couple of perspectives can be brought out of this fact. Although most foreign PhD students are fee paying, teaching to students at this level needs to be provided by relatively senior scholars. This can be contrasted by the large proportion of undergraduate teaching which is done by junior and often casually-employed academics ${ }^{20}$. Another point is that many foreign PhD graduates will leave Australia after their training, by visa requirements or by choice, meaning that considerable effort is put into educating elite, qualified students who will not be able to add anything to Australia's human resources.

## Students enrolled in a Course leading to provisional registration as a medical practitioner

The aim of this section is to follow the development of enrolments in programmes to produce an initially-registered medical work force. It is possible to use the higher education statistics system to a certain extent, because there is a field in the higher education collection that if completed correctly by universities, should enable a closer look at the group of students in question.

Table 3.17 summarises what is available from the system, and the material of interest is 'Course leading to provisional registration as a medical practitioner', which have represented about one per cent of the total across the period in question, but their number increased strongly, by 118 per cent. The period in question saw the creation of several new medical schools, and well as the rebadging of medicine as a postgraduate course over the years at some universities.

Tables 3.18 and 3.19 relate only to the 'medical practitioner' row, in order to demonstrate what has happened this century in the university training of medical students. Figures for the years shown have been taken directly from uCube, and therefore represent exactly what has been reported to the Department by universities.

Table 3.18 presents enrolments by 'medical practitioner students', by course level, gender and citizenship status. The table shows that there has been a switch from these students being undergraduates, to becoming postgraduates. By 2015, a quarter of the cohort of students were enrolled as postgraduates. The gender distribution indicates that the proportion of women slightly exceeds 50 per cent, but the proportion of women in 2007 had been 55 per cent. Finally, Table 3.18 indicates that the proportion of overseas students has increased from 16 per cent at the start of the century, to 20 per cent by 2015 .

Table 3.19 examines the distribution of 'medical practitioner' students according to university within State/Territory. On the basis of these figures, Queensland has increased its share of the medical practitioner pie the most, with an additional 3,191 enrolments, or 277 per cent between 2002 and 2015. This is against the national increase of 118 per cent. Within Queensland, it would appear that Bond University and Griffith University have started to train such students. However, the pattern at Griffith is odd, with there being no enrolments in courses leading to provisional registration as a medical practitioner in 2012, but with enrolments in all other years since they first reported such students in 2005. James Cook increased the number of these students by 982 , or 414 per cent. Monash also seemed to expand its training in this area considerable this century, by 1,582 students, or 182 per cent. The table shows a decline in enrolments since 2007, but this is a reflection of the way that university now trains its medical practitioner students.

Enrolments by 'medical practitioner' students in the state of Western Australia show a couple of interesting patterns. First, the University of Notre Dame enrolled its first students in 2005, and by 2015, had enrolments by 879 such students. The other matter relates to the University of Western Australia. As outlined in Chapter 1, UWA moved to a graduate school-style model from 2012. Therefore, there would be a decline in the number of 'medical practitioner' enrolments from that year, as future intending medical practitioners enrolled in say, a BSc for three years, prior to commencing a postgraduate pre-registration medical degree. Under such circumstances, 2015 was perhaps the first year that postgraduate enrolments would be accepted into the new course.

Looking at other patterns of enrolment around the country, equivalent enrolments to those at UWA can be seen in the enrolment pattern at the University of Melbourne. Looking at ANU, it would seem that this university also started to train medical practitioners during the period, starting with an apparent intake of 80 in 2004, with the total population of these students peaking at around 370 .

The next chapter examines student load patterns for the STEM fields of education and for courses leading to provisional registration as a medical practitioner.

## Chapter 4

# STEM Student Load: STEM Teaching and learning in the 21st century 

The system for counting students and measuring what they study at university can be examined in more detail by considering 'equivalent full-time student load' (EFTSL), which is built up from the subjects that students take as part of the course they are enrolled in. (See also Chapter 1). This measure therefore allows us to consider what is being taught by Australian universities, and the students it is being taught to. A full-time student enrolled in a 'normal' work load for a student in a given degree or diploma will produce an EFTSL of 1.000. The typical way that student load is reported is according to which disciplines are taught, but neither the Department's standard tables, nor its uCube on-line cross tabulation software allow a researcher to see which groups of students are being taught. Although it is useful to know how much mathematics (for example) is being taught, it is also helpful and useful from a planning perspective to know which students are receiving that teaching, and particularly if the proportion is changing over time. The type of question that can be answered if information is made available in that way includes the one asked by the ACDS last century, when they wanted to know how the 'average' BSc had changed over time. As was revealed at the time, the proportion of the enabling sciences (chemistry, mathematics and physics) in the 'average' BSc had declined, while the proportion of biological sciences and non-science subjects had increased. ${ }^{21}$ Before the data files were removed from the Department's website, it was possible to undertake such analysis without purchasing tables from the Department.
'Student Load' (EFTSL) is calculated by summing the weights attributable to the subjects that students enrol in (e.g., a subject that constituted ten per cent of a full year's work is weighted as 0.100 EFTSL), and there are two aspects of this. First, by summing the weights in all 'chemistry' subjects, for example, it is possible to calculate how much 'chemistry' is taught. Second, by filtering this information, it is possible see how much 'chemistry' is taught to students in different courses at various course levels, and further, to establish whether there have been variations in these patterns according to other variables, such as whether students are female or male, domestic or overseas, or commencing or continuing their programmes (to pick the binary populations analysed in this study). In line with the Field of Education classification, Discipline Groups can be broad (two-digit), narrow (four digit), or detailed (six digit). Very little information is reported below the two-digit level, which is the extent of detail available via uCube.

## Teaching STEM 2002-2015

Starting with the overall situation, Table 4.1 shows the distribution of student load according to the discipline of the subjects that are being taught, first at the level of Broad Discipline Groups. One minor issue with tables in this chapter is that the nature of the detail of what is being examined means that it was necessary to construct them from purchased tables. Unfortunately, there are minor differences between some of these purchased tables and what the figures produced in the Department's formal publications, and its on-line cross-tabulation system uCube show. In order to have a consistent set of numbers in this chapter, arguably the main chapter in this study, it is necessary for all the numbers in this chapter to tally internally. That said, the differences are not great. A comparison with

[^11]Table 2.7, for instance, shows that the figure generated by uCube for teaching in the Natural and Physical Sciences in 2015 was 122,373 EFTSL, whereas in Table 4.1, the figure that ought to be identical, is 122,397 EFTSL. Of course, it is a mystery how some of the slippage has occurred between STEM and non-STEM disciplines. The so-called privacy issue is about the potential for identifying individuals, yet student load is not a measure of individuals. For example, the 8,704 EFTSL shown in 2002 for Agriculture, Environmental and Related Studies is not 8,704 people. It is perhaps ten or 20 times that number, because it is the aggregation of every subject in this discipline being taken at any level, at every university teaching in this discipline, to every student enrolled in a course in any field. And these myriad 'agriculture' students are enrolled at 38 or so universities, across Australia.

Table 4.1 shows that teaching in STEM disciplines (to all students, at all course levels) increased by 44 per cent, from 174,550 EFTSL in 2002 to 252,128 EFTSL, with Natural and Physical Sciences and Engineering and Related Technologies providing most of that growth. The table also shows that teaching in Agriculture, Environmental and Related Studies also increased quite strongly ( +45 per cent), but this Broad Discipline Group is quite small. Information Technology teaching declined by over 9,000 EFTSL, or 17 per cent. Growth of teaching in non-STEM disciplines exceeded that in STEM disciplines by a considerable margin.

Table 4.1 Student Load: All Students by Broad Discipline Group. Numbers, Percentage \& Growth: 2002 - 2015

Source: The Department: Purchased Tables.
Within each broad discipline group are narrow discipline groups, and within each of those, detailed discipline groups. The next set of tables provide information down to the detailed level for the four Broad Discipline Groups that make up STEM. Tables 4.2 to 4.5 have been split into two sections to facilitate identifying any trends.

Table 4.2 concerns the Natural and Physical Sciences Broad Discipline Group, starting with Table 4.2a, which shows the narrow discipline groups in that Broad Discipline Group. Overall, teaching in the Natural and Physical Sciences to students in all courses at all levels increased by 48,661 EFTSL, or 66 per cent, with considerable variation within the narrow discipline groups. The largest of the narrow discipline groups is Biological Sciences, teaching in which also increased by the most: by 17,936 EFTSL, or 59 per cent. There was also strong growth in Mathematical Sciences: $+11,920$ EFTSL, or 58 per cent. Growth in the teaching of Chemical Sciences was 52 per cent, followed by 41 per cent growth in Physics and Astronomy and 34 per cent in Earth Sciences. The largest proportionate growth occurred in 'Other Natural and Physical Sciences'. More will be mentioned about this in the commentary below concerning detailed discipline groups.

Table 4.2 b drills down even further. Although having information at this level would provide excellent and detailed information for descriptive, reporting and planning purposes, a brief examination of this table reveals a number of unfortunate glitches. These glitches arise from the manner in which some universities (and perhaps the Department) have interpreted instructions for coding subjects to
discipline groups. The point of conjecture arises from whether or not universities should have codes any subjects to the ' 00 ' (i.e., to 010500 in the case of Chemical Sciences). There has been an apparent decline of 41 per cent of subjects in this category, with increases in the other three values available. It would seem, therefore that some universities coded chemistry subjects that were not specifically ‘010501 Organic Chemistry’ or ‘010503 Inorganic Chemistry' as '010599 Chemical Sciences not elsewhere classified', whereas others have coded such subjects as '010500 Chemical Sciences'. In 2007, which happens to be one of the years examined in this report, and one for which I still have the data sets withdrawn by the Department in 2011, two-thirds of the student load coded as 010500 Chemical Sciences was reported by just seven universities, with the Universities of Sydney (699 EFTSL), Melbourne ( 647 EFTSL) and Monash University ( 631 EFTSL) being the largest 'contributors'.
Given this situation, one would be inclined to aggregate 010500 and 010599 for the Chemical Sciences Broad Discipline Group to create a set of numbers fully comparable across the sector. However, there is no equivalent catchall category within the narrow discipline group Physics and Astronomy. One wonders why this should be the case. Perhaps this situation is of little importance, but if that is so, why does the Department continue to collect information from universities at this level of detail? Why not simply collect information at the Narrow Discipline Group level? At the very least, the Department should request that universities examine their propensity to code subjects to '019999 Other Natural and Physical Sciences - nec' ('not elsewhere classified'). Is there no other place within the more than 30 other detailed discipline groups for these apparently unclassifiable subjects to be linked?

Bearing in mind these provisos, a couple of changes at the detailed discipline level should be noted. Within Biological Sciences, Human Biology has presented the largest numerical increase: $+10,709$ EFTSL, or 138 per cent. Biological Sciences nec also increased handsomely: $+4,426$ FTSL, or 193 per cent. Of course, much of this increase could be due to the decline of 3,311 EFTSL in 010900 Biological Sciences.

The 'Other Natural and Physical Sciences' narrow discipline group requires further examination. The first thing is that detailed disciplines 019900 and 019999 together increased by about 200 per cent. One has to wonder what these 'other natural and physical sciences' subjects are that cannot be fitted into the 30 or so categories for the specific narrow discipline groups (such as Physics and Astronomy), plus the five specific detailed disciplines that exist within 'Other Natural and Physical Sciences'. It is also interesting to see that in 2015, Australian universities were providing training for 688 equivalent full-time forensic sciences (up from 193 EFTSL in 2002). Some might see this number as being in excess of potential demand. According to the ABC : 'Forensics is a highly specialised career and there are only a few employment opportunities in the occupation'. ${ }^{22}$

Finally, a further indicator of change in university statistics that has nothing to do with policy changes etc, is that the ' 00 ' codes, such as 010100 for Mathematical Sciences and the equivalents for all narrow discipline groups except 'Other Natural and Physical Sciences' declined over the course of this century to the tune of 8,225 EFTSL. If one were still permitted to have access to the data files that were freely available for data from the early 1990s until 2009, we could work out where these changes had occurred, and perhaps why. Of course, the Department is in a position to do such work, but with few exceptions over the years, they have shown little interest in undertaking deeper analysis of the rich data demanded from universities. This is a pity, because the Department's personnel are now the only ones with the capacity to research into some matters.
Commentary on the other STEM Broad Discipline Groups will be briefer than for Natural and Physical Sciences, given the variability inherent with aspects of the figures at the detailed discipline group level.

Source: The Department: Purchased Tables. Nec: 'not elsewhere classified'
Table 4.3 examines the teaching of Information Technology subjects to all students at all levels. Only narrow discipline group Other Information Technology increased over the period with the exception of 020111 Data Structures, which has managed to increase by one EFTSL since 2002. Of course, as was the case with the Natural and Physical Sciences, the 'Other' category of Information Technology disciplines increased handsomely, in an otherwise declining market. Universities were apparently unable to classify some Information Technology subjects more specifically than 'IT nec / Other IT'.

Table 4.3 Student Load: All Students in Information Technology Subjects by Narrow and Detailed Discipline Groups. Numbers, Percentage \& Growth: 2002-2015

Source: The Department: Purchased Tables. Nec: 'not elsewhere classified'
Table 4.4 relates to the Engineering and Related Technologies Broad Discipline Group. In the first part of the table, it can be seen that rates of growth by narrow discipline group varied from six per cent (Electrical and Electronic Engineering, and 214 per cent in Civil Engineering, averaging 93 per cent overall. In numeric terms, growth varied from 46 EFTSL in the miniscule Automotive Engineering narrow group, to 10,249 EFTSL in Civil Engineering. Perhaps it is known within the engineering profession why the growth in Civil Engineering has been quite so spectacular. In the case of the largest narrow discipline group: Electrical and Electronic Engineering, perhaps the modest expansion was related to the decline in the numbers of students enrolled in Information Technology courses. Strong growth was also demonstrated by Mechanical and Industrial Engineering and Process and Resources Engineering. As with other discipline groups, the category 'Other Engineering and Related Technologies' expanded by nearly 9,000 EFTSL ( +197 per cent). To repeat the question asked twice already relating to the expansion of the 'Other' narrow discipline groups, why is it that a taxonomy that contains something like 80 options within engineering-related detailed discipline groups is it possible for there to be so much expansion in the 'Other...' category?

Source: The Department: Purchased Tables. Nec: 'not elsewhere classified'
Table 4.5 replicates the information above for the Agriculture, Environmental and Related Studies Broad Discipline Group. As the table shows, only the Agriculture and Environmental Studies narrow discipline groups expanded to any extent during the period under consideration. Proving to be an exception to the rule, Other Agriculture, Environmental and Related Studies narrow discipline group did not expand over the period.

The second section of the table further demonstrates the variability in how universities have coded the subjects they teach. For example, 050100 Agriculture declined by 502 EFTSL, but 050101 Agricultural Science expanded by 881 EFTSL. Overall, the Agriculture narrow discipline group expanded by 690 EFTSL. Overall, Environmental Studies increased by 3,774 EFTSL.

## STEM: women and men

It is well known that women are in the majority in the Australian university student population, but women's presence is not evenly distributed across university courses. Among female-majority fields, from uCube we find extremes in areas such as programmes for initial nurse education and teacher education ( 86 per cent of enrolments are women in both cases), and for veterinary science registration ( 77 per cent). At the other extreme, the proportion of women in fields such as Engineering and Related Technologies and Information Technology is around 17 per cent.

In Table 2.3 we saw that the overall long-term Australian university student population is distributed approximately $55: 45$ in favour of women. Further, from Table 3.3, we know that in 2015, women made up 53 per cent of enrolments in bachelor's degree courses in Agriculture, Environmental and Related Studies, 50 per cent of those in the Natural and Physical Sciences, and as mentioned above, about 17 per cent of enrolments in Engineering and Related Technologies and Information Technology. However, we are also aware that service teaching can mean that students in non-STEM programmes can still receive teaching in STEM disciplines. For example, it is likely that nursing students receive teaching in biology and information technology. Therefore, this aspect of 'service teaching' should be examined, to see how the gender spread pans out within the STEM disciplines, that is, examining the distribution of student load at the level of narrow discipline groups. Figures 4.1 to 4.4 explain.

The average female uptake of subjects in the Natural and Physical Sciences overall was just over half in all years examined, with considerable variation within the narrow discipline groups. (See Figure 4.1). Across all courses at all levels, enrolment in subjects in the Biological Sciences was the most favoured by women. The proportion of women has in fact dropped slightly since 2002, but women receive more than 60 per cent of the teaching in this narrow discipline group. A slightly lower proportion of teaching is taken by women in Other Natural and Physical Sciences, but nonetheless, the proportion exceeded 60 per cent across the period. However, it should be noted that this narrow discipline group comprises five defined detailed discipline groups (Medical Science, Forensic Science, Food Science, Pharmacology and Laboratory Technology), plus any other teaching that universities were unable to fit within the discipline group taxonomy. The gender distribution may not be the same across these groups.

Chemical Sciences is the next narrow discipline group favoured by women, with the proportion of women dropping slightly since 2002, but was still about half in 2015. Subjects in the relatively small Earth Sciences narrow discipline group have moved from women comprising just over 40 per cent of the total, to just under 40 per cent by 2015. The proportion of the students taking subjects in the Mathematical Sciences has been slightly under 40 per cent this century.

Finally, Physics and Astronomy is the least attractive Broad Discipline Group for female students, declining from about 29 per cent in 2002, to about 27 per cent in 2015.

Figure 4.1 Student Load 2002-2015: Natural \& Physical Sciences - Female \%

Figure 4.2 examines the proportion of teaching to female students in the Information Technology narrow discipline groups. Overall, the proportion of students taking subjects in informational technology dropped from about 28 per cent 24 per cent over the period, but as shown in the graph, there are variations within the three narrow discipline groups. Only Information Systems subjects have had a female audience exceeding 30 per cent of the total in the 2000s.

Readers will have noticed that even if enrolments by women in Information Technology courses amounted to about 17 per cent of all enrolments in that Broad Field of Education, but that women receive in excess of 20 per cent of all the teaching in the Information Technology discipline group. The reason for this variation can be explained by service teaching in IT subjects that are taken by students in non-Information Technology courses in other fields of education.

Figure 4.2 Student Load 2002-2015: Information Technology - Female \%

Figure 4.3 presents similar information about the ten narrow discipline groups that make up the Engineering and Related Technologies Broad Discipline Group. Manufacturing Engineering and Process Engineering (within which one can find chemical engineering as the largest single category) have the highest proportion of women in their classes, but this proportion has scarcely reached 30 per cent.

Figure 4.3 Student Load 2002-2015: Engineering and Related Technologies - Female \%

Finally, in this brief examination of STEM and gender, Figure 6.4 looks at the Broad Discipline Group of Agriculture, Environmental and Related Studies. As can be seen, the narrow discipline groups of Agriculture, and Environmental Studies both had more than half of audiences made up by women, with lower proportions of women in the other narrow discipline groups.

Figure 4.4 Student Load 2002-2015: Agriculture, Environmental \& Related Studies - Female \%

## What do students in STEM courses study?

The answer to this question is no doubt that students in STEM courses predominantly study STEM subjects, but of course, most STEM courses (particularly at the undergraduate level) are also likely to include some non-STEM subjects. This section, therefore, examines the what students in STEM courses are studying, by comparing STEM fields of education (courses) with STEM (and other) discipline groups (the subjects in those courses). Among other things, by comparing student enrolments with load, it is possible to measure the amount of service teaching. Most will be aware that educating Australia's student population involves a great deal of cross-disciplinary teaching and service teaching (provided by departments in one faculty / department / discipline to students from another faculty / department / field of education). That is, the subjects a student enrols in are neither necessarily restricted to a single discipline, nor to those taught by a single academic department or faculty.

This section presents analysis that extends beyond the STEM fields of education and discipline groups. In light of the important role of 'science' as service teaching to courses across the university spectrum, this section of the study also considers the teaching to students enrolled in courses in the Health and Society and Culture fields of education. Both of these broad fields of education cover a wide range of sub-fields, and for that reason, Health has been divided into 'medicine', 'pharmacy, optical science and dental studies', 'veterinary studies', and 'other health', the main constituent of which is nursing. In the case of Society and Culture, courses in Behavioural Science have been split out from Law and all other minor fields of education.

Table 4.6 presents a student load table shows the amount of teaching students in STEM and non-STEM courses received, which some non-STEM fields have been expanded. This table can be compared with Table 3.1, showing that the patterns are similar. STEM enrolments increased by 32 per cent between 2002 and 2015 (See Table 3.1), and teaching to students in STEM courses increased by 35 per cent (Table 4.6). The student load shown in Table 4.2 to students in courses in each Field of Education could be in any discipline. For example, the 79,691 EFTSL taught to students in Engineering includes teaching in the Engineering discipline, as well as all other teaching received by those students (such as teaching in mathematics, physics and chemistry, all of which are from the Natural and Physical Sciences discipline). In line with enrolments in broad fields of study, the table shows that there has been strong growth in the Natural and Physical Sciences and Engineering and Related Technologies, minimal expansion in Agriculture, Environmental and Related Studies, and decline in Information Technology.

Overall, teaching to STEM students increased by 35 per cent over the period, compared with growth in teaching to students in non-STEM courses of 68 per cent.
Looking at patterns in Health, it can be seen that there has been strong growth in all sub-categories. It should be noted that the overall expansion in these courses was 132 per cent between 2002 and 2015, with relatively lower growth in medical studies (+103 per cent) compared with the rest of Health. In Behavioural Sciences, the size also doubled, far stronger growth than there had been in the rest of the minor fields within Society and Culture.

Perhaps more interesting is the information provided in Table 4.7, which presents broad analysis for 2015 of what students in STEM courses (all levels) were studying in 2015. This table is split into three sections: EFTSL (numbers); the distribution of this teaching to students by Field of Education; and the distribution of this teaching according to the Discipline Group of that teaching. Taking Engineering as an example, Engineering students received teaching amounting to 79,691 EFTSL, of which 60,011 EFTSL was in Engineering disciplines. Therefore, for Engineering students, about 75 per cent of the teaching they received was in Engineering disciplines, as shown in the second part of the table. These students also received 14 per cent of their teaching in Natural and Physical Sciences subjects, plus one per cent in Agriculture, Environmental and Related Studies, four per cent in Information Technology subjects, and seven per cent in non-STEM disciplines. (Minor rounding errors apply). Table 4.7 also shows that subjects in Engineering and Related Technologies weighted at 71,201 EFTSL were taught, 84 per cent of which was taught to students in Engineering programmes, eight per cent to students in other STEM fields of education, and eight per cent to students in non-STEM programmes. The bottom part of the table demonstrates that Engineering is a relatively low provider of service teaching, compared with say, the Natural and Physical Sciences disciplines. In the latter, only 48 per cent of teaching of is provided to students enrolled in courses in the Natural and Physical Sciences Broad Field of Education, with 12 per cent going to other STEM fields of education, and 39 per cent to students not enrolled in STEM courses.

\# Includes additional detail for Health and Society and Culture fields of education.
FoE: Field of Education; DG: Discipline Group
Looking at teaching to students enrolled in courses in Society and Culture, particularly in the Behavioural Sciences narrow Field of Education, it can be seen that eight per cent of the teaching is in subjects within the Natural and Physical Sciences Broad Discipline Group (see middle of table), and that this teaching to Behavioural Sciences students represented two per cent of all Natural and Physical Sciences in 2015.

## Drilling down: Bachelor's Degrees

As revealed in Table 2.2, bachelor's degree enrolments represented 66 per cent of all enrolments in 2015, down from 70 per cent in 2002. This section focuses on bachelor's degrees because this course level has the main impact on what happens in teaching and learning, even if its relative proportion of total enrolments has declined. Table 4.8 shows the distribution of all teaching by Broad Discipline Group to students enrolled in all bachelor's degrees. The disciplines are shown as being grouped into STEM and non-STEM disciplines. Among teaching in the STEM disciplines, Information Technology experienced 'negative growth' ( -31 per cent), but the other STEM components grew at a faster rate than the growth in bachelor's level teaching across the sector. Engineering and Sciences also grew faster than Non-STEM disciplines overall. Teaching in Agriculture, Environmental and Related Studies represents only about one per cent of all teaching at the bachelor's level. Engineering increased its proportion slightly, from six to seven per cent, as did teaching in the Natural \& Physical Sciences ( 13 per cent in 2002, rising to 14 per cent in 2015). Overall, STEM teaching at the bachelor's level dropped from 29 per cent to 26 per cent, because of the decline in Information Technology teaching. Among the non-STEM disciplines, there was strong growth in Health (increase from none per cent to 15 per cent), with less growth in the Creative Arts and Management \& Commerce. Teaching in Society and Culture at the bachelor's degree dropped by three per cent to 25 per cent of the total.

Source: The Department: Purchased Tables.
This study is principally concerned with STEM, and the next several tables consider changes in bachelor's level courses in the STEM fields of education. The tables compare the situation in 2002 with that in 2015, considering the teaching (STEM and Non-STEM) to students in each of the four STEM groups of courses. The tables show the contribution of STEM teaching at the level of Narrow Discipline Group, and teaching in non-STEM disciplines at the Broad Discipline Group level. The reason for examining STEM at the narrow discipline group level is to see what has changed over time in the composition of STEM university degrees.

Table 4.9 presents a summary of teaching and learning in 2002 and 2015 involving students enrolled in bachelor's degree courses in the individual STEM fields of education and all other fields, and the teaching in all disciplines to those students. In this table, broad fields of education are shown as the columns, and the rows show teaching to students in those broad fields of education according to the Broad Discipline Groups of the subjects being studied by the bachelor's degree students in question. Because of its size, Table 4.9 has been split into two: firstly, showing the actual EFTSL involved in 2002 and 2015, and secondly, the change between 2002 and 2015 (predominantly growth).

Taking bachelor's degree students in the Natural and Physical Sciences as an example, the table should be read as follows. Students enrolled in BSc and other bachelor's degree courses classified by universities within the Natural and Physical Sciences in 2002 were enrolled in Natural and Physical Sciences subjects equivalent to 27,739 EFTSL, out of a total of the 39,748 EFTSL of subjects that such students were enrolled in toto. This means that 'science' bachelor's degree students took about 70 per cent of their total teaching in 'science' subjects. Further, they were enrolled in subjects in the three other STEM fields that amounted to about 3,500 EFTSL (about nine per cent of the total), including Information Technology subjects equivalent to 1,694 EFTSL. By 2015, expansion in the number of bachelor's degree students in the Natural and Physical Sciences Broad Field of Education meant that
the total teaching received by these students had increased to 66,418 EFTSL, an increase of 26,670 EFTS, or 67 per cent. Of this teaching, 45,398 EFTSL was in subjects in the Natural and Physical Sciences disciplines, slightly more than 68 per cent of all the teaching received by these students. Another 6,495 EFTSL of teaching in the other STEM disciplines was also received, nearly ten per cent of all teaching to these students.

Bachelor's degree students in Natural and Physical Sciences courses also study subjects outside the STEM disciplines. In 2002, the main sources of service teaching to bachelor's degree students enrolled in Natural and Physical Sciences courses were subjects in the disciplines of Health and Society and Culture. Teaching provided from Society and Culture sources was 5,430 EFTSL, more than three times the amount of teaching received in the other STEM disciplines. A portion of this teaching was in Law, likely to be to students enrolled in combined degrees in science and law. Service teaching in Health disciplines was about 50:50 from medicine and other health disciplines.
The columns for Information Technology, Engineering and Related Technologies, and Agriculture, Environmental and Related Studies present similar information to that given for bachelor's degree students in the Natural and Physical Sciences. In the case of Information Technology, the decline in enrolments has been mentioned in several places above. In 2002, teaching in Information Technology bachelor's degree students was about two-thirds of all the teaching they received. The amount of teaching to these students declined by nearly 14,000 EFTSL ( -60 per cent) by 2015 , but the proportion of teaching in Information Technology subjects to these students increased to 72 per cent of the total. The main sources of service teaching to Information Technology bachelor's degree students came from subjects in the Natural and Physical Sciences, Engineering and Management and Commerce. These patterns from 2002 persisted to 2015.

In the case of students enrolled in bachelor's degree courses in Engineering and Related Technologies, there was an expansion of total teaching of 17,947 EFTSL ( +45 per cent), including growth of 16,779 EFTSL in Engineering subjects. These 'engineering' students received 63 per cent of all their teaching in Engineering and Related Technologies disciplines in 2002, and this proportion increased to 72 per cent by 2015. The major other sources of teaching to bachelor's degree students in Engineering and Related Technologies were the Natural and Physical Sciences, Information Technology, Management and Commerce and Society and Culture. There was no growth in the teaching in Society and Culture subjects over the period. The proportion of teaching provided to engineering students from outside the STEM disciplines was much lower than was the case for students in the Natural and Physical Sciences. In 2002, this teaching comprised 14 per cent of the total, but this proportion declined to ten per cent by 2015 .

The final STEM Field of Education to be examined here with respect to what bachelor's degree students are studying is Agriculture, Environmental and Related Studies. This Field of Education / Discipline Group is a relatively small part of Australian higher education. As a Field of Education, it represents 1.3 per cent of all bachelor's degree students, and a similar proportion as a Broad Discipline Group. Table 4.9 shows that in 2002, bachelor's degree students in Agriculture, Environmental and Related Studies Related Studies were provided with 9,102 EFTSL in 2002, and that this declined to 8,896 EFTSL by 2015 (-206 EFTSL; -two per cent). In 2002, these students received about 42 per cent of their teaching in Agriculture, Environmental and Related Studies discipline subjects, and another 36 per cent in Natural and Physical Sciences.

Source: The Department: Purchased Tables. FoE: Field of Education; DG: Discipline Group

Another 19 per cent of teaching came from non-STEM disciplines. The main change to be noted is huge increase in teaching to Agriculture, Environmental and Related Studies students of subjects in the Broad Discipline Group Architecture and Building. In 2002, 66 equivalent full-time students enrolled in Agriculture, Environmental and Related Studies courses received teaching in subjects in the Architecture and Building Broad Discipline Group. By 2015, this figure had risen to 829 full-time equivalent students, an increase of 1,156 per cent. Nearly all of this increase can be explained by introduction of the Melbourne Model by the University of Melbourne from 2008, and the fact that the Bachelor of Environments programme, intended as the undergraduate precursor to eventual registration as an architect, was classified in the Agriculture, Environmental and Related Studies Broad Field of Education. Please refer to the appropriate section of Chapter 1 for an explanation of this phenomenon.

## Natural and Physical Sciences Courses

Tables 4.10 to 4.13 examine student load for the students enrolled only in bachelor's degrees in the Natural and Physical Sciences, including BSc and other courses at bachelor's level within this field. Table 4.10 considers what students study as part of their Natural and Physical Sciences bachelor's degree in more detail: to the level of 'narrow' Field of Education. Tables 4.11 and 4.12 provide further information on critical binary populations: female and male students, and domestic and overseas students. This is followed by Table 4.13, which compares commencing students with continuing students. Roughly speaking, commencing students tend to be in the first year of their degree, and continuing students in subsequent years. By comparing the two, it is possible to see if students persist with subjects in some disciplines more than they do in others. If the number of equivalent full-time students in a narrow discipline group is considerably lower for commencing students than it is for continuing students, it is a prima facie indication that some subjects are 'starter' subjects. This pattern is replicated below for the other STEM fields of education.
Table 4.10 shows that teaching to Natural \& Physical Sciences bachelor's degree students increased by 67 per cent between 2002 and 2015, comprising an increase in STEM teaching of 66 per cent, and in non-STEM disciplines of 71 per cent. The proportion of STEM teaching received by these bachelor's degree students in 2002 was 79 per cent of all the teaching they received, declining slightly to 78 per cent by 2015 . There was a reciprocal increase of teaching in non-STEM disciplines. Of the STEM teaching received by Natural and Physical Sciences bachelor's degree students, the rate of growth was 64 per cent, but the proportion of teaching from this source declined from 70 per cent in 2002 to 68 per cent in 2015. These Natural and Physical Sciences bachelor's degree students received a relatively low proportion of teaching in other STEM disciplines in both years shown in Table 4.7. In 2015, teaching in Information Technology constituted three per cent of all teaching received, with equivalent proportions in Engineering and Agriculture, Environmental of four per cent and three per cent, respectively.

Among the non-STEM disciplines in 2015, Natural and Physical Sciences bachelor's degree students received about 12 per cent in Society and Culture disciplines, five per cent in Health disciplines and two per cent in Management and Commerce disciplines. The proportion of non-STEM teaching in Society and Culture disciplines had been slightly higher in 2002 (14 per cent).

[^14]Table 4.11 considers the teaching to female and male students in bachelor's degrees in courses in the Natural and Physical Sciences. By 2015, the majority of these 'science' students were women, but only just. This fact was shown in Table 3.3, which showed enrolments by women and men (among other things). Table 4.11 distributes the genders according to the subjects they are undertaking as part of their degree. Overall, the proportion of teaching to women in bachelor's programmes in the Natural and Physical Sciences was 51 per cent, down from 56 per cent in 2002. Within this overall result, there are several gender-based variations. Some these are shown, and others can be calculated from the table. In 2002, 54 per cent of the teaching to women in science bachelor's degrees was in STEM subjects, but this declined to 49 per cent by 2015. Teaching to male students is the reciprocals of these percentages: 46 per cent in 2002, and 51 per cent in 2015 . On the other hand, 62 per cent of the teaching in non-STEM disciplines to students in bachelor's degrees in the Natural and Physical Sciences was to women, but this figure dropped to 57 per cent in 2015.

Within the STEM disciplines, in 2015, 52 per cent of the teaching in subjects linked to the Natural and Physical Sciences was to women, down from 57 per cent in 2002. In the other STEM disciplines, female students received 19 per cent of the teaching in Information Technology (down from 30 per cent in 2002), and 23 per cent of the teaching in Engineering and Related Technologies. Of the teaching in Agriculture, Environmental and Related Studies to students enrolled in bachelor's degree students, 49 per cent of it was to women in 2015 (down from 54 per cent in 2002).
Looking within the Natural and Physical Sciences Broad Discipline Group, the gender distributions also vary. In 2015, 59 per cent of the teaching in Biological Sciences was to women (down from 63 per cent in 2002), and women were also in the majority in 'Other Natural and Physical Sciences', the narrow discipline to increase the most within the Natural and Physical Sciences. However, here too there was 'leakage' towards male students. Women enrolled in bachelor's degrees in the Natural and Physical Sciences received 64 per cent of the total teaching in this narrow discipline group in 2002, down to 57 per cent in 2015. It should be noted that teaching in the enabling sciences of mathematics, physics and chemistry to women is much lower than that to men, and the proportions are declining. In 2002, 45 per cent of the teaching in Mathematical Sciences was to women, but this dropped to 37 per cent by 2015. In Physics and Astronomy, women's proportion of the teaching declined from 38 per cent to 29 per cent. Women received the majority of the teaching in Chemical Sciences in 2002, but this declined to a shade under 50 per cent by 2015. Women's proportion of teaching in Earth Sciences, the smallest narrow discipline group within the Natural and Physical Sciences, also dropped, from 44 per cent to 38 per cent between 2002 and 2015.

Table 4.11 also shows the distribution by narrow discipline group of teaching to 'science' bachelor's degree students in Information Technology, Engineering and Related Technologies and Agriculture, Environmental and Related Studies. Within Engineering disciplines, the main narrow disciplines providing the most teaching to 'science' students in 2002 were Process Engineering and Electrical and Electronic Engineering. However, there was considerable growth in the amount of teaching to bachelor's degree students in the Natural and Physical Sciences in Civil Engineering, Mechanical and Industrial Engineering and Geomatic Engineering. Again, one can speculate that this growth is also a reflection of there being more 'science' students intending to become engineers.

Table 4.11 provides a distribution (by gender) of the change between 2002 and 2015 as to what constitutes a bachelor's degree in the Natural and Physical Sciences. The distribution of STEM and non-STEM disciplines taken 'science' students did not change: 76 per cent of women and 81 per cent of men took their science degrees from STEM disciplines, with the reciprocal 24 per cent and 19 per cent for male and female students, respectively, being taken from non-STEM subjects. For female bachelor's degree students in the Natural and Physical Sciences, in 2002, eight per cent of their degrees was in mathematics, three per cent in Physics, etc., with subjects from Natural and Physical

Sciences narrow discipline groups totalling 71 per cent. In the other STEM disciplines, Information Technology subjects made up two per cent, one per cent were in Engineering and Related Technologies subjects, and two per cent were in Agriculture, Environmental and Related Studies subjects. Twentyfour per cent of the subjects taken by women as part of their bachelor's degree in the Natural and Physical Sciences were in non-STEM disciplines. By 2015, these proportions changed little. The biggest change occurred in Other Natural and Physical Sciences (from six to 12 per cent of the total degree), but the proportion of subjects in Biological Sciences also declined.

Male students in bachelor's degrees in the Natural and Physical Sciences drew more heavily from the STEM disciplines than did their female counterparts. Men took 81 per cent of their course-wide study load from STEM, but a lower proportion of this came from subjects in Natural and Physical Sciences disciplines than women. However, men studied subjects in Information Technology (four per cent in both 2002 and 2015), Engineering and Related Technologies (six per cent), more than women did.

Among non-STEM disciplines, Subjects in Society and Culture were the biggest source of non-STEM teaching received for both sexes, followed by Health and Management and Commerce. Women had a greater propensity to include subjects from among the Health disciplines. The Society and Culture Broad Discipline Group includes both law and behavioural studies / psychology, both of which have been of interest to 'science' students. In the case of law, some students will be undertaking join degrees such as BSc/LLB.

Table 4.13 examines the distribution of teaching between commencing bachelor's degree students, and students other than those commencing, described here as 'continuing'. The point of this analysis is to see if any particular disciplines come out (in effect) as being studied as first year, perhaps compulsory subjects, that students then drop once they have finished first year. Although the definition of 'commencing student' is more complex than merely new-to-university students starting first year, to a considerable extent, that is what the 'commencing students' represents, particularly where fulltime bachelor's degree students are concerned.
Table 4.13 shows that the composition of a bachelor's degree course in the Natural and Physical Sciences in 2002 comprised 75 per cent of subjects in Natural and Physical Sciences disciplines, eight per cent were taken from other STEM disciplines, and 18 per cent were non-STEM subjects. There were only minor changes in this pattern by 2015; in effect, there was a small decline in the proportion made up by subjects in the Natural and Physical Sciences, and a compensating increase in the uptake of non-STEM subjects. However, attention should be paid to the so-called enabling sciences of mathematics, physics and chemistry fall into this category. Commencing students' degrees comprised 14 per cent of mathematics subjects in 2015 ( 15 per cent in 2002), but continuing students' bachelor's degrees in the Natural and Physical Sciences made up only eight per cent. Physics and Astronomy subjects made up six per cent of a commencing student's course in 2015 ( 7 per cent in 2002), but only three per cent of continuing students' work load in subsequent years. For chemistry, the uptake by
commencing students dropped from 17 per cent to 14 per cent, but continuing students' uptake of chemistry dropped to six per cent in 2015 (seven per cent in 2002). The fact that the proportion of a commencing student's uptake of say, mathematics is lower than the proportion of mathematics in a continuing student's work load indicates that many students drop mathematics after first year. That is, relatively low proportion of first year mathematics students continue with studies in mathematics.

Looking at the other discipline groups within the Natural and Physical Sciences, uptake of subjects in the Biological Sciences for both commencing and continuing students declined, and there were increases in the teaching of subjects in Other Natural and Physical Sciences. Earth Sciences remained a small discipline group among both commencing and continuing bachelor's degree students, and in both years examined here. Just as many students cease to enrol in the enabling sciences after first year, the opposite is the case in the other narrow disciplines within the Natural and Physical Sciences Broad Discipline Group. In the case of Biological Sciences, for example, the pattern is that more students pick up biological sciences subjects as they progress through their bachelor's degree.

The points to take away from this examination include the use of students' uptake of enabling sciences disciplines as preliminary to the study plans of many of them; the continuing relative strength of the Biological Sciences, but to a lesser extent than in the past; and perhaps the relatively low uptake by bachelor's degree students in Natural and Physical Sciences courses of subjects in the other STEM disciplines.

While examining change in what students in bachelor's degrees in the Natural and Physical Sciences are studying, Figure 4.5 shows changes in the narrow disciplines being studied. The columns show the actual EFTSL for each narrow discipline group within Natural and Physical Sciences. In conjunction with Table 4.7, we can see that the Biological Sciences are by far the most 'popular' with bachelor's degree students enrolled in courses in the Natural and Physical Sciences, although the overall proportion of teaching to science students declined (from 50 to 46 per cent between 2002 and 2015). Mathematical Sciences teaching represented 15 per cent of total Natural and Physical Sciences teaching in both years shown, having increased from 4,139 EFTSL to 6,803 EFTSL. The proportion of this 'science' teaching provided to 'science' students declined slightly in Physics and Astronomy, Chemical Sciences and Earth Sciences, and only 'Other Natural and Physical Sciences' showed proportionate increase. The 'Other' category includes Medical Sciences, Forensic Sciences, Food Science and Biotechnology, Pharmacology, Laboratory Technology, and 'Other - not elsewhere classified'. This latter category can often be an indication of universities being vague or even lazy, by not coding the subjects they teach carefully.

Figure 4.5 Student Load: Comparison of Teaching of Natural and Physical Sciences Subjects to Students in Natural \& Physical Sciences Bachelor's Courses - 2002 \& 2015 - EFTSL - No.

Figure 4.6 Student Load: Comparison of Teaching of Natural and Physical Sciences Subjects to Students in Natural \& Physical Sciences Bachelor’s Courses - 2002 \& 2015 - EFTSL - \%

Figures 4.5 and 4.6 clearly expose what has happened this century to the 'BSc' degree. Apart from growth of interest in 'Other Natural and Physical Sciences', there has been little change in the relative popularity of the 'science' disciplines, or the proportions of the other STEM disciplines (Information Technology, Engineering and Related Technologies, and Agriculture, Environmental and Related Studies), or even the non-STEM disciplines. However, if one goes back to 1989, the shape of a 'science degree' has changed considerably. In 1989, teaching in the mathematical sciences comprised over 17 per cent of what science students studied 23 , but by 2002 , this was down to ten per cent. Similarly, there were declines in the extent of teaching in the chemical sciences and physical sciences, and a compensating increase in the biological sciences, from about one-quarter to over one-third. The issue here is that there was a considerable change from the pattern of 'science' study in the 1980s compared with the situation this century. Exact precision is not possible due to the changes in the groupings of courses and subjects and the counting methodology that occurred in 2001 and 2002 (See Chapter 1).

## Information Technology Courses

The apparent decline of interest in programmes in Information Technology is well known and has been mentioned in various parts of this study. The impact of this decline within the STEM disciplines shown in Table 4.14 was by 51 per cent in Natural and Physical Sciences disciplines (particularly in the Mathematical Sciences -1444 EFTSL, or -52 per cent), 38 per cent in Information Technology disciplines, and 38 per cent in Engineering and Related Technologies disciplines, particularly in Electrical and Electronic Engineering ( -50 per cent). Information Technology bachelor's degree students receive little teaching in Agriculture, Environmental and Related Studies disciplines. The decline in teaching from the non-STEM disciplines was 45 per cent, leading to an overall decline of teaching received of 36 per cent.

Table 4.15 presents similar analysis relating to male and female students enrolled in bachelor's degree courses in Information Technology. The impact of the Melbourne Model on bachelor's-level

[^16]enrolments in IT courses must also be borne in mind. In addition to the decline in Information Technology enrolments every year from 2003 to 2011, the University of Melbourne's intake into IT courses became an expanded intake into bachelor's degrees in Natural and Physical Sciences.

[^17]Table 4.15 summarises the differences in the context of what makes up a bachelor's degree course in Information Technology between female and male students. The answer to this implied question seems to be that there is little difference based on gender. It is also the case that there was relatively little difference in what constituted a bachelor course in Information Technology in 2015 compared with 2002, particularly for women. For male students, their uptake of subjects in the Information Technology discipline group increased slightly. Service teaching from the Natural and Physical Sciences is all but restricted to Mathematical Sciences and nearly all the subjects taken in Engineering and Related Technologies are in Electrical and Electronic Engineering. Among non-STEM disciplines, the majority of subjects taken are provided in Management and Commerce, and Society and Culture. The general propensity is that a larger proportion of female students take subjects from non-STEM disciplines.

Looking at the make-up of bachelor's degrees in Information Technology, from Table 4.16 it can be seen that Overseas students tend to draw a higher proportion of their studies from Information Technology subjects than do domestic students, and domestic IT students study more subjects in the Natural and Physical Sciences, especially in Mathematical Sciences. As already noted, Information Technology bachelor's degree students taking Engineering and Related Technologies students do so predominantly from Electrical and Electronic Engineering.

Table 4.17 presents similar information for bachelor's degree students in Information Technology according to their commencing status. As can be seen, in 2015, teaching to these students in 2015 was less than half of what it had been in 2002. The proportion of Information Technology bachelor's degrees drawn from IT subjects has increased over the period, for both commencing and continuing students, and the proportion provided from the Natural and Physical Sciences discipline group declined, particularly in Mathematical Sciences. Of course, for a student enrolled in a degree in Information Technology, 'science' teaching represents service teaching, and one would expect such teaching to predominate in earlier years, particularly in first year. Of the teaching received in Engineering and Related Technologies, most is in the narrow discipline of Electrical and Electronic Engineering.

## Engineering and Related Technologies Courses

Tables 4.18 to 4.21 show the distribution of teaching to students in bachelor's degree courses in Engineering and Related Technologies: overall, by gender, by citizenship status, and by commencing status. Table 4.18 shows that these students receive most of their teaching in STEM disciplines ( 93 per cent in 2015, up from 90 per cent in 2002). It increased by 45 per cent over the period, comprising an increase of 50 per cent in the STEM disciplines taught to bachelor's degree students in Engineering and Related Technologies programmes, and three per cent in non-STEM disciplines.

Source: The Department: Purchased Tables. FoE: Field of Education; DG: Discipline Group
Engineering bachelor's degree students received 72 per cent of their teaching in Engineering and Related Technologies disciplines in 2015, up from 63 per cent in 2002. Teaching from the Natural and Physical Sciences disciplines increased by 30 per cent over the period, but the proportion of 'science’ teaching dropped from 19 per cent to 17 per cent between the two years. Non-STEM teaching represented only seven per cent of all teaching in 2015 (down from ten per cent in 2010).

Table 4.19 allows for a comparison of what constitutes an engineering bachelor's degree for women and men. Along with Information Technology, Engineering and Related Technologies is the other field in which women are in an extreme minority. In 2015, women represented less than 16 per cent of all bachelor's degree enrolments. According to the subjects these students study, there are only minor variations between what women and men study to qualify in engineering, unlike the situation with male and female students enrolled in bachelor's degree courses in the Natural and Physical Sciences. Perhaps the largest variation is to be found with Process and Resources Engineering, which is the Narrow Discipline Group within which chemical engineering falls. Female engineering students were also likely to be taking Chemical Sciences subjects, within the Natural and Physical Sciences narrow discipline group. The changes that have occurred over time have done so in tandem, with the proportion of an 'engineering' degree constituted by engineering subjects has gone up, while the proportion of teaching in Information Technology and non-STEM disciplines declined.

Table 4.20 looks at the uptake of bachelor's degrees in Engineering and Related Technologies according to whether they are domestic or overseas students, who made up 28 per cent of the total in 2015. There are several variations in what domestic and overseas students study in their Engineering and Related Technology bachelor's degrees. For example, it can be seen in Table 4.20 that domestic students tend to draw more heavily from subjects in the Natural and Physical Sciences, but Mathematical Sciences is the biggest single 'science' discipline for both domestic and overseas students. Domestic students also take more Information Technology subjects, but the overall proportion declined between 2002 and 2015. Overseas students take rather more subjects in Engineering and Related Technologies.

Table 4.21 looks at commencing and continuing students in bachelor's degrees in Engineering and Related Technologies. The fact that subjects in the Natural and Physical Sciences disciplines feature predominantly among commencing students confirms that first year engineering degrees often comprise 'science' teaching, before students move into the bulk of their training in engineering. Among commencing students, teaching in science disciplines (especially in Mathematical Sciences and Physics and Astronomy) are important. The proportion of these disciplines taken by continuing engineering bachelor's degree students is much lower than for commencing students. The proportion of engineering degrees made from Information Technology subjects declined between 2002 and 2015, and engineering students appear to have little linkage to subjects in Agriculture, Environmental and Related Studies. Also, the proportion of teaching in non-STEM disciplines declined, but commencing students are less likely to take these subjects than continuing students.

## Agriculture, Environmental and Related Studies Courses

Agriculture, Environmental and Related Studies is a relatively small part of Australian higher education. As a Field of Education, it represents 1.3 per cent of all bachelor's degree students, and a similar proportion as a Broad Discipline Group. As noted earlier, the Melbourne Model has disrupted the historical time series in several ways, including the way things look for the Agriculture, Environmental and Related Studies Broad Field of Education. Referring to Table 4.22, shows growth in the extent of teaching to Agriculture, Environmental and Related Studies bachelor's degree students. In 2002, 66 equivalent full-time students received teaching in subjects in the Architecture and Building Broad Discipline Group. By 2015, this figure had risen to 829 equivalent full-time students. In the overall scheme of things, neither of these figures is significantly large, but for anyone
seeking to analyse apparent trends in the Agriculture, Environmental and Related Studies broad Field of Education, it represents a serious perturbation. Refer to Chapter 1 for an explanation of changes in the time series in Agriculture, Environmental and Related Technologies.

From Table 4.23 it is possible to compare enrolment patterns by gender. The main changes appear to be the proportion of service teaching to Agriculture, Environmental and Related Studies bachelor's degree students from Natural and Physical Sciences (down from 36 per cent to 26 per cent for women; 36 per cent to 29 per cent for men), with increases in the proportion of teaching from the Architecture and Building Broad D2iscipline Group.

[^18]Patterns of learning by students enrolled in bachelor's degree courses in Agriculture, Environmental and Related Studies have probably changed more than any of the other STEM fields of education. Looking at the study patterns of domestic and overseas students enrolled in 2002, overseas students enrolled in these courses drew 47 per cent of their teaching from subjects in the Natural and Physical Sciences, (cf. 36 per cent for domestic students), but this declined considerably, to 18 per cent in the case of overseas students, and more modestly, to 29 per cent for domestic students. The proportion of teaching in Engineering subjects stayed the same for domestic students (about four per cent), but for overseas students, the proportion increased from three to seven per cent between 2002 and 2015. Proportions of teaching in Agriculture, Environmental and Related Studies subjects changed in opposite directions between 2002 and 2015 for overseas and domestic students. The proportion for domestic students increased from to 43 to 45 per cent, but for overseas students, there was a decline from 32 to 29 per cent.

Source: The Department: Purchased Tables. FoE: Field of Education; DG: Discipline Group
The biggest change, and on the surface and unlikely change for agriculture and environmental studies students, has been the huge increase, particularly for overseas students, of teaching in subjects in the Architecture and Building Broad Discipline Group. The proportion of teaching from
these disciplines to both domestic and overseas students in 2002 was one per cent. In 2015, for domestic students, the proportion had risen to seven per cent, but for overseas students, 24 per cent of teaching to these students was in Architecture and Building subjects. In fact, overseas students from all around the country received one EFTSL of teaching in Architecture and Building in 2002, increasing to 331 EFTSL in 2015. Coincidentally, this change of pattern matches the introduction of the Melbourne Model.

Turning now to commencing and continuing students enrolled in Agriculture, Environmental and Related Studies bachelor's degrees, teaching in the natural and physical sciences is also been important, but has declined over the period shown, particularly in the Biological Sciences. In 2002, subjects in the Natural and Physical Sciences made up nearly half of what a student starting their studies in agriculture, forestry or environmental science took, but this declined to 37 per cent by 2015. The science work load taken on by continuing students also declined. Another pattern change can be seen in the Engineering and Related Technologies discipline group: there has been a considerable increase in the teaching in Mechanical Engineering, and the overall proportion of teaching in engineering subjects increased from two per cent to four per cent. Only the Department can work out
what is behind these changes. Access to the data files that we all had until the 2009 academic year could provide the level of detail required.

The next section repeats the analysis above for PhD students, albeit at a much-reduced level of detail.

## Drilling down: PhDs

The PhD is an important degree in the STEM disciplines, particularly in the Natural and Physical Sciences. The PhD represents a barrier to entry in many academic and research markets.
Table 4.26 summarises the teaching at the PhD level by broad discipline group. Overall, PhD teaching increased by 62 per cent between 2002 and 2015, with STEM disciplines providing 47 per cent of all teaching at this level in 2015, up from 40 per cent in 2002. Growth was particularly strong in Engineering and Related Technologies ( $+3,678$ EFTSL, +145 per cent). The overall proportion of PhD-level teaching increased from ten per cent to 15 per cent in this Broad Discipline Group. PhD teaching in the Natural and Physical Sciences is now the largest, at 24 per cent of all PhD teaching in 2015.

The next-highest taught disciplines are in Society and Culture (21 per cent in 2015, down from 26 per cent in 2002), and Health 15 per cent. The largest increases occurred in the Natural and Physical Sciences ( $+3,942$ EFTSL), Engineering and Related Technologies $(+3,678)$ and Health $(+3,069)$. In contrast with most matters relating to Information Technology, there was expansion of 855 EFTSL ( +88 per cent) over the period.

Table 4.26 Student Load: PhD Students by Broad Discipline Group, 2002-2015

Tables 4.27 and 4.28 repeat the information in Table 4.26 in more detail. Both tables show the distribution of PhD students in 2002 and 2009 by narrow discipline group in teaching in the STEM disciplines, according to gender (Table 4.28), and citizenship status (Table 4.29). These tables allow an examination of these two important binary groups, to seek differences in the pattern of what each student group studies. The percentage columns show the distribution of all teaching to students enrolled in PhDs in the two years examined.
Table 4.27 shows gender differences among PhD students in their propensity to study at this level. In 2002, 32 per cent of female PhD students were studying in the STEM disciplines, compared with 48 per cent of male PhD students. Within the STEM disciplines, women were more likely than men to be studying Information Technology, Engineering and Related Technologies and Agriculture, Environmental and Related Studies. Within the Natural and Physical Sciences, women were more likely than men to be studying in the Biological Sciences, and there were more female than male students undertaking PhD studies in Other Natural and Physical Sciences. In fact, around 70 per cent of female PhD students in the Natural and Physical Sciences were enrolled in a programme in either

Biological Sciences, or Other Natural and Physical Sciences (cf. about 52 per cent of equivalent male PhD students). Overall, however, 54 per cent of the student load in the Natural and Physical Sciences was to male students. Elsewhere it has been shown that women are under-represented in Engineering and Related Technologies and Information Technology, in which 21 per cent and 24 per cent respectively of teaching was to women.
Perhaps the main gender-related variation between 2002 and 2015 was the increased proportion of all PhD teaching to male students in the Engineering and Related Technologies discipline. PhD studies in Engineering increased from 15 per cent of all PhD teaching, to 22 per cent. At the same time, the proportion of male students undertaking PhD studies in STEM disciplines increased from 48 per cent to 57 per cent of the PhDs taken by men. However, the proportion of STEM PhDs taken by women also increased: from 32 per cent to 37 per cent. In the case of women, in 2002, 32 per cent of all PhDs were in Society and Culture disciplines, which declined to 25 per cent in 2015.

Table 4.28 shows patterns and differences in PhD uptake by domestic and overseas students. There was strong growth at the PhD level, particularly by overseas students. Their proportion of the total increased from 20 per cent to 38 per cent between 2002 and 2015. There was also a considerable switch in favour of the STEM disciplines. In 2002, 61 per cent of all teaching to overseas students at the PhD level was non-STEM disciplines, but by 2015 , the proportion declined to 38 per cent.

Source: The Department: Purchased Tables.
The growth was particularly strong with overseas PhD students taking the Engineering and Related Technologies discipline, in which there was a six-fold increase from 630 EFTSL in 2002 to 3,618 EFTSL in 2015. There was also strong expansion in the Natural and Physical Sciences discipline, with an almost five-fold increase from 889 EFTSL to 4,230 EFTSL.

The final table so far as PhD students are concerned is Table 4.29, which has been split into two parts in order to examine teaching to PhD students in the specific STEM fields of education, and all PhD students in non-STEM PhDs. Considering students enrolled in 'science' PhDs, Table 4.27 shows, unsurprisingly, that Science PhD students predominantly study from the Natural and Physical Sciences discipline group. In 2002, 92 per cent of the teaching to these students was in Natural and Physical Sciences disciplines, with some teaching in Agriculture, Environmental and Related Studies disciplines (one suspects, in Environmental Science), with teaching also from Health, and Society and Culture. It is likely that the latter teaching is in Behavioural Sciences. There was considerable expansion in PhDs in the Natural and Physical Sciences ( +73 per cent).
Looking at PhDs in Information Technology, the number (expressed in EFTSL) more than doubled between 2002 and 2015. Most of the teaching to these students is from the Information Technology disciplines (about 95 per cent in both points of measurement).

The situation for Engineering and Related Technologies PhD students is similar. There was strong overall growth ( +118 per cent), and most of the teaching to these students is in Engineering and Related Technologies disciplines ( 91 per cent in 2002, and 96 per cent in 2015).

Teaching to PhD students in Agriculture, Environmental and Related Studies is much less restricted to Agriculture, Environmental and Related Studies disciplines. About 25 per cent of teaching to these PhD students was from other Broad Discipline Groups in 2002, and 23 per cent in 2015.

## Drilling down: Students enrolled in a course leading to provisional registration as a medical practitioner

Chapter 3 presented enrolments of 'students enrolled in a course leading to provisional registration as a medical practitioner' (see Tables $3.16-3.18$ ) according to several variables. The next two tables present more information about that cohort of students. The tables show data from 2005 (the first year for which these data were made available) to 2015. Table 4.30 shows that the amount of teaching to this cohort increased from 9,435 EFTSL to 18,063 EFTSL, an increase of 91 per cent. In 2005, about ten per cent of this teaching was provided in the Natural and Physical Sciences Broad Discipline Group, with very little teaching being provided in disciplines other than Health. Within the Health Broad Discipline Group, the great majority of the teaching was within the minor Discipline Group 'Medicine'. No surprises there, perhaps.

Looking at the teaching to 'medical practitioner' students in subjects from the Natural and Physical Sciences discipline group, one can only wonder about the apparent volatility of the numbers. Why did
the amount of teaching in the Natural and Physical Sciences drop by over 41 per cent between 2010 and 2011? Does this have something to do with the introduction of graduate school models, and the shift of medical practitioner students at some universities to become postgraduates? To answer such questions would require access to the data files that used to be available to the public.

Table 4.31 takes a closer look at teaching within the Natural and Physical Sciences Discipline Group. The overall teaching of 'science' to these students has not kept pace with the expansion in the number of 'medical practitioner' students, but at least some of the reason for that is that some students now start their studies in a degree classified as other than 'Health - Medicine'. However, of the teaching to these students within the Natural and Physical Sciences, there has been an apparent switch away from the Narrow Discipline Group of 'Biological Sciences', into 'Other Natural and Physical Sciences'. Teaching from the other Narrow Discipline Groups has always been quite low. As stated earlier, the only way to examine this more closely would be to be able to access the information submitted to the Department by universities in finer detail. Under current arrangements, only the Department itself would be able to do so.

The next chapter presents an examination of course completions in the STEM fields of education between 2002 and 2015.

## CHAPTER 5

## STEM Course Completions 2002-2015

This chapter provides a closer look at award course completions in the STEM Fields of Education between 2002 and 2015. The tables and graphs in this chapter have been prepared from larger tables purchased from the Department. Because of concerns about privacy and the potential for individual students to be identified from university statistics, the Department uses a technique called input perturbation that means that they don't necessarily report the actual figure ${ }^{24}$. I mention this because it is possible for figures obtained from legitimate sources to vary by small amounts. In the tables, Total Completions usually exceeds Total Students because some students complete more than one course in the same year (such as combine course students graduating with both a BSc and an LLB).

Table 5.1 looks more closely at the composition of STEM course completions cf. non-STEM course completions in 2002 and 2015, by level of course. The number of STEM course completions (all course levels) was 47,194 in 2002 , which rose to 61,783 in 2015, a 31 per cent increase, as noted in Chapter 2. The proportion of STEM course completions declined from 23 per cent of all completions in 2002, to 18 per cent in 2015. Non-STEM course completers numbered 159,183 in 2002, rising to 272,646 in 2015. The largest number of completers of STEM qualifications receive a bachelor's degree ( 38,317 in 2015), followed by 12,405 completions in master's by course work degrees. However, the overall proportion that bachelor's degrees made up of all STEM degree completions declined, from 67 to 62 per cent, whereas the proportion of master's by coursework completions increased from 15 to 20 per cent of all STEM completions. Note that I have used the term 'PhD' throughout this chapter, but the Department's official nomenclature is 'doctorate by research'.
The distribution of graduates within the STEM fields of education altered considerably over the period, due specifically to the relative decline of Information Technology. In 2002, course completions in Information Technology were 39 per cent of the total, but by 2015, this proportion had declined to 22 per cent. Meanwhile, completions in the Natural and Physical Sciences increased from 30 to 39 per cent, and in Engineering, from 23 to 33 per cent. Agriculture, Environmental and Related Studies completions declined slightly as a proportion (from eight to seven per cent).

[^20]The importance of the PhD in the STEM fields is clear from this table: in 2002, graduations in the STEM fields of education at the doctorate by research course level constituted 43 per cent of all graduations at this level in 2002, and the proportion had risen to 47 per cent by 2015.

Table 5.2 considers course completions by women. In 2002, the 16,236 female STEM course completers made up 14 per cent of all female course completers (i.e., 86 per cent of women completing courses were in non-STEM programmes), but this proportion declined to 11 per cent by 2015, during which year 20,731 STEM qualifications were awarded to women. Completions of STEM programmes overall show that 72 per cent of completions were at the bachelor's level, and this proportion declined to 66 per cent by 2015. However, there were variations within STEM fields. For example, in Natural and Physical Sciences, 78 per cent of completions by women were at the bachelor's level (down from 87 per cent in 2002). Proportions of completions at the bachelor's level were lower in the other fields of education. The proportion of completions at the bachelor's level in non-STEM fields in 2002 was 67 per cent, but this proportion declined to 57 per cent by 2015.

Table 5.2 also shows growth in completions between 2002 and 2015. Overall, 4,495 more women completed STEM programmes ( +28 per cent), but there was a decline in Information Technology completions of 2,343 (- 47 per cent). These figures should be compared with the 72 per cent growth in qualifications in non-STEM fields.

Women increased their presence in PhD-level qualifications in STEM fields by 136 per cent overall, with a particularly enhanced showing in PhD completions in Engineering, Technology and Related Technologies ( +235 completions; +294 per cent.). There was also strong increase in Information Technology (+ 267 per cent), but numbers are lower than in the other STEM fields.

Source: The Department: Purchased Tables
Looking at course completions by male students, male STEM graduations made up 14 per cent of all male students completing courses in 2002, the same proportion as for women. (See Table 5.3, and cf. Table 5.2). The STEM proportion of all course completions doubled to 28 per cent by 2015. This situation should be compared with the relative decline of completions in STEM programmes by women. Growth overall between 2002 and 2015 represented 33 per cent, including growth in Natural and Physical Sciences completions and Engineering and Related Technologies completions of 83 and 84 per cent, respectively. The decline in Information Technology completions over the period kept the overall STEM increase lower than it would have been. There had been nearly 31,000 course completions in STEM fields in 2002, rising to just over 41,000 in 2015.

Completions in bachelor's degrees represented the majority course level, with the 19,858 STEM bachelor's degree completions representing 64 per cent of the 30,958 completions at all levels in 2002. The equivalent proportion in 2015 had declined to 60 per cent of all. The proportion of course completers at bachelor's level was greater in the Natural and Physical Sciences ( 79 per cent and 76 per cent of the total in 2002 and 2015, respectively), with lower proportions in the other STEM fields of education.

Table 5.4 provides scope for comparing the patterns of change in numbers of course completions
between women and men. This table shows numbers of completions for all students, and the proportion of these by women. System-wide, course completions by women in 2015 represented 57 per cent of all completions, but women represented 62 per cent of non-STEM course completions, and 34 per cent of STEM completions. This $62: 34$ split was also the case in 2002. Within STEM, women were responsible for 52 per cent of completions in the Natural and Physical Sciences and in Agriculture, Environmental and Related Studies, but only 20 per cent and 17 per cent of the completions in Information Technology and Engineering and Related Technologies, respectively.

Source: The Department: Purchased Tables
Table 5.5 considers domestic students, a group which represented 79 per cent of all enrolments in 2002 and 74 per cent in 2015. Among domestic students in STEM programmes, 74 per cent completed bachelor's programmes in 2015, compared with 60 per cent of domestic students in non-STEM programmes. The comparative figures for overseas students were 41 and 44 per cent, respectively, in 2015 (see Table 5.5). Domestic students, therefore, are more likely to be pursuing bachelor's degree-level studies. Within the STEM fields, domestic students were more likely to have pursued bachelor's-level studies in the Natural
and Physical Sciences ( 82 per cent in 2015) than in the other STEM fields. Equivalent proportions for the other three STEM fields were 67 per cent in Information Technology, 66 per cent in Engineering and Related Technologies and 63 per cent in Agriculture, Environmental and Related Studies.
Growth in the number of STEM completions amounted to a 70 per cent increase ( $+6,462$ completions, all levels), with variations within the STEM fields: Natural and Physical Sciences increased by 7,030, or 78 per cent; Engineering and Related Technologies increased by 3,859 completions, or 50 per cent. However, the number of completions in Information Technology and Agriculture, Environmental and Related Studies programmes declined over the period.

Source: The Department: Purchased Tables

Table 5.6 records course completions by overseas students. From Table 4.3, we know that overseas students now comprise over one-quarter of the students enrolled in Australian university courses, up from 20 per cent in 2002, and the number of overseas students almost doubled between 2002 and 2015. Therefore, there has also been considerable expansion in course completions by overseas students, with the total number increasing from 49,379 in 2002 to 107,550 in 2015. This is a growth rate of 118 per cent. Within the STEM fields, the growth was less spectacular, at 58 per cent.

[^21]Table 5.7 allows for comparison between changes among overseas and domestic students. It shows numbers of all completions in 2002 and 2015, and the proportion of these made up by overseas students. Overseas students produce a larger proportion of course completions than their overall presence among university enrolments would suggest. In recent years, overseas students have been about 26 per cent of enrolments, yet in 2015, they produced 32 per cent of all course completions. Within the STEM fields, they generated 36 per cent of all completions in 2015. The main reason for this is because they are more highly represented in shorter programmes, typically at the masters by coursework and other postgraduate levels. Within STEM fields, overseas students are also more highly represented at the PhD level.

[^22]Tables 5.8 to 5.11 show numbers of course completions by course level, by university, for each of the STEM fields of education. Table 5.8, for instance, presents these results for course completions for students enrolled in courses in the Natural and Physical Sciences, followed by equivalents for the other three STEM fields of education. Purchased tables were used, because neither the published tables available on-line, nor those that can be confected oneself via the uCube system, allow for PhDs , master's by research and master's by coursework completions to be shown separately.

The impact of the alleged threat to individual privacy is evident in these tables, with non-declaration of the actual figures for cells with fewer than five observations, and 'not published' ('np'). To explain (if such is necessary), taking the first row in Table 5.8, data for Charles Sturt University for 2015, the total number of completions (all levels) was 218 , comprising 125 bachelor's degrees, 75 'other postgraduate' completions, and 13 master's by coursework completion. Two course levels produced fewer than five completions. Given that the missing observations total five, perhaps there were three completions at master's by research level, and two at other undergraduate level.

In other places, the Department's stealth programme has decided not to report (for example) the number of PhD graduations at the University of New England in 2015. On the basis of the numbers that we have been permitted to see, it can be discerned that there must have been between six and nine PhDs awarded that year. Given the nature of PhD awards, I fancy that if anyone could be bothered to do so, they could access freely-available information on the UNE website, to see exactly how many PhDs were awarded at ceremonies in 2015, and perhaps even their names and UNE affiliations. However, I digress. There is little point in providing much commentary on these tables. Surfeit it to say, it is possible to see which universities awarded qualifications in the STEM fields in 2002 and 2015, with detailed information provided for 2015.

Source: The Department: Purchased Tables
Earlier in this text, and in earlier examinations of science enrolments, student load and course completions, I noted that Australian higher education institutions have an extensive list of narrow and detailed fields of education. However, the existence of this list does not necessarily assist in providing additional detailed information about what qualifications students are ending up with. There are two main reasons for this. First, some courses, particularly at the bachelor's level, are generic in nature, and it is not easy to classify them to a narrow or detailed level. For example, students in BSc degrees tend to start with a broad spread of subjects, before narrowing their focus somewhat by final year. For such courses, it is not possible to classify the situation below the Broad Field of Education 'Natural and Physical Sciences'. However, by the time students are completing PhD-level qualifications, one might have expected that the ensuing degree would be highly specialised.
Table 5.12 shows course completions at the PhD level in 2015 in the Natural and Physical Sciences field of education. There are five options at the 'narrow' field of education classification, with the category '0199 Other Natural and Physical Sciences'. This category comprises individual detailed fields of education in Medical Science; Forensic Science; Food Science and Biotechnology; Pharmacology; plus Natural and Physical Sciences 'not elsewhere classified'. It would seem that some universities are not very specific in how they could their course completions, with Go8 members Monash and the University of Western Australia standing out, and among other universities, perhaps Western Sydney University. In 2015, Monash, it would seem, graduated 167 PhD biologists and fewer than five mathematicians, but reported no PhDs in physics, chemistry or earth sciences. However, they did graduate 100 'Other Natural and Physical Sciences' PhDs. UWA produced 70 in this catchall category, and $<5$ earth scientists.

Perhaps the main 'problem' with this lack of specificity by universities is that if any agency, national or international, asks, for example, 'how many PhDs were awarded in Chemical Sciences in 2015', the answer from the Department will likely be ' 226 '. However, this answer will underestimate the real number to the extent that there has been non-specific reporting by universities.

The 'Total' column shows the numerical total of that column, but the narrow field of education columns are 'estimates' based on the likely value of the ' $<5$ ' cells. Sometimes it is obvious what the cell values are.

Note: A total of 84 course completions are included in the cells marked as $<5$.
Numbers of PhD graduation in Information Technology are many fewer than in the Natural and Physical Sciences, with 301 PhDs having been awarded in 2015. Many of us are perhaps uncertain about the differences between 'computer science' and 'information systems', not to mention 'other Information Technology'. Monash, Griffith and Federation Universities awarded information technology PhDs in this third category.

In the case of Engineering, the University of New South Wales is the most prolific producer of PhD graduates in Engineering and Related Technologies, followed by the University of Queensland and Monash University. Monash, it would seem, graduated 108 chemical engineers, and another nine in fields of education other than the ones specified. See Table 5.14.

\# UTas total includes five completions in 0317 Maritime Engineering, which has been left out of the tables for reasons of space.
Finally, in 2015, the system produced 410 PhD graduates, in the Agriculture, Environmental and Related Studies, with the most coming from the University of Western Australia. All of these were in Agriculture. Griffith University, the Australian National University and James Cook University produced the most PhD graduates in Environmental Studies.

## Students enrolled in a Course leading to provisional registration as a medical practitioner

The final aspect of course completions covered in this chapter relates to students enrolled in a course leading to provisional registration as a medical practitioner. This cohort was also examined in the third and fourth chapters in the context of enrolment and student load patterns, respectively.

Table 5.16 is a composite table that shows the number of completions by course level, gender and citizenship status. Between 2002 and 2015, the number of medical practitioner course completions increased by 163 per cent, from 1,420 to 3,733 . The first medical practitioners to graduate with a postgraduate qualification occurred in 2013 (Flinders University), followed by the University of Melbourne, Griffith University and ANU from 2014. In 2015, 682 (18 per cent) of total completions in this cohort graduated with a postgraduate qualification. The other 15 universities seem to have stayed with the 'traditional' undergraduate system providing training for registration as medical practitioners ${ }^{25}$.

The gender distribution over the period has seen just more half of medical practitioner graduates being women. In line with the overall proportionate growth in Overseas students, their proportion increased from 11 per cent in 2002, to 19 per cent in 2015.

Table 5.17 presents a summary of medical practitioner graduations by university, ranked according to the number of completions in 2015. That year, Monash graduated 502 medical practitioners, a number that was 216 per cent larger than the number of completions in 2002. The next-largest university in this context was the University of Queensland, which had produced many more graduates than Monash in 2002. The Universities of Melbourne, Sydney and New South Wales were the next in line.

Source: The Department. uCube
Finally, Table 5.18 looks at an aspect of the 'medical practitioner labour force' issue, by comparing the number of domestic graduations by state / territory. New South Wales universities produced 26 per cent of medical practitioner graduates in 2015, but that state contains 30 per cent of the Australian Population. There is a smaller mismatch in Victoria. However, Queensland, Western Australia, South Australia and the ACT all produce a slightly higher proportion of the medical practitioner course completers than reflected in their state-based populations. The Northern Territory does not have a medical school.

Table 5.18 Course Completions: Domestic Students enrolled in a Course leading to provisional registration as a medical practitioner, by State / Territory, 2002-2015

[^25]
## 6. Conclusion

This century has seen radical changes in Australian higher education, and these have been described in the text. However, a brief recap is in order. The principal aim of this study was to undertake a detailed examination of patterns of participation in the so-called STEM fields of education of science, technology, engineering and mathematics, and the arrangement of Australian higher education makes this a feasible objective. Additional material on teaching to students in Health and Society and Culture courses has also been included, but it is less easy to map changes for programmes that cannot be defined according to a 'broad' Field of Education. Whereas we can be fairly certain about what is being measured in in the broad Field of Education Engineering and Related Technologies, this is not the case within broad Field of Education Health, which in addition to 'medicine', also includes nursing, dental science, veterinary science, various health therapies, and even 'complementary medicine'. However, by using the 'special course' variable in the statistical collection, some information has been provided about 'students enrolled in a course leading to provisional registration as a medical practitioner', one of the 'special courses' identified in the collection.

This study has provided information about university enrolments, student load and course completions from 2002 to 2015, and some of the broad trends have been reiterated below. However, analysts and policy also need to be aware that changes that could easily be missed have changed the scope of what the statistics mean. These issues were laid out in the introduction and have been mentioned again at various places in the text.

Looking at overall patterns in the 21st century, STEM enrolments (at all levels) declined as a proportion from 24 per cent (2002) to 20 per cent (2015). Within this overall relative decline in STEM enrolments, there has been growth of about 46,000 students in courses in the Natural and Physical Sciences, and 45,000 in Engineering and Related Technologies. The numerical growth in these two fields of education was counteracted in part by the apparent steady-state situation in Agriculture, Environmental and Related Studies programmes, and a decline of over 18,000 enrolments in courses in Information Technology. Overall, there were nearly 73,000 more enrolments in STEM programmes in 2015 cf . 2002, but this figure must be compared with increases in Management and Commerce $(+129,000)$, Health $(+124,000)$, and Society and Culture ( $+112,000$ ). Growth in STEM enrolments was 32 per cent, compared with 66 per cent in non-STEM fields.

Women became the majority of the university population during the 1980 s. Women have tended to be more common in the non-STEM fields of education, but by 2015, they made up about half of enrolments in Natural and Physical Sciences and Agriculture, Environmental and Related Studies, but their presence in Engineering and Related Technologies (17 per cent) and Information Technology (19 per cent) was the lowest of any fields of education.
Overseas student numbers have been on a quite steep growth trajectory for many years, but particularly this century. In the 21st century, growth in overseas student enrolments increased from over 185,000 to over 363,000 enrolments ( $+178,045$, or 96 per cent) between 2002 and 2015. In doing so, overseas students' proportion of all enrolments increased from 21 per cent to 26 per cent. The proportion had reached as high as 27 per cent in 2007.

Within the STEM fields of education, both overseas and domestic students increased their number by more than 36,000 between 2002 and 2015 . However, the proportion of overseas students increased from 24 per cent in 2002 per cent to 30 per cent in 2015. Overseas students in non-STEM fields of education increased their proportion from 18 per cent to 23 per cent over the period. Growth in overseas students
was strongest in Engineering and Related Technologies, in which the rate of growth was about 180 per cent, and these students increased their presence from 22 to 36 per cent over the period.
The largest purveyor of STEM training among Australian universities was the University of New South Wales in both 2002 and 2015. The other major STEM players are the Universities of Melbourne, Queensland and Sydney, as well as Monash University and RMIT. Adding to these universities UTS and Curtin University of Technology, Australia had nine universities with more than 10,000 STEM students in 2015.

Another enrolment trend has seen the proportion of enrolments in undergraduate degrees decline, and an increase in the proportion of students in 'other postgraduate' courses. This decline was less in the Natural and Physical Sciences than in other fields of education, and part of the reason for this could be the impact of the new 'graduate school' arrangements at the Universities of Melbourne and Western Australia, which added about 3,000 new enrolments in the Natural and Physical Sciences, matched by compensating declines in bachelor's degree enrolments in the other STEM fields of education, as well as other areas from outside the STEM fields, such as medicine, and in Melbourne's case, Architecture and Building.

The broad patterns with university enrolments described above have been replicated by the number of students eventually completing the university qualification they were enrolled in. Of course, the patterns with course completions is that they lag behind enrolment patterns.

Despite the relatively comprehensive coverage provided by the Department's on-line table-building uCube system, one area that uCube does not shed light is how the composition of study programmes changes over time. For example, uCube will not allow the analyst to see how the composition of (say) bachelor's degrees in the Natural and Physical Sciences has changed. Nor can this information be gleaned by referring to tables published by the Department, because such information is simply not provided in those tables. Therefore, purchasing custom-made tables is the only way to see, for example, the changes in the composition of bachelor's degrees. In a nutshell, uCube permits one to see changes in the amount of teaching over time at the Broad Discipline Group level, but not which students are studying those disciplines. Similarly, uCube provides no insights at the Narrow Discipline Group level, although the Department does publish a few tables that show the amount of teaching at the narrow discipline group level. ${ }^{26}$

Although useful, such tables do not show how the composition of courses in 'science' (or any other field of education) has changed over time. Earlier studies showed that the content of the average 'science' degree had changed ${ }^{27}$, and in particular, the relative decline in the 'enabling sciences' of chemistry, mathematics and physics was noted. Looking at bachelor's degrees in the Natural and Physical Sciences in the 21st century, such relative declines are still evident. As Table 4.10 of this study revealed, although Mathematical Sciences teaching represented ten per cent of the teaching to 'bachelor of science' students in both 2002 and 2015, teaching in the Chemical Sciences declined from 11 per cent to nine per cent, and in Physics and Astronomy from five per cent to four per cent.

Although comparisons back to 1989, when the first study for the ACDS was undertaken, would be interesting, they can be at best imperfect. Since 1989, major changes have occurred in the way courses

[^26]and subjects were aggregated, and the methodology for counting students changed. For instance, a student undertaking a 'science' degree with majors in computer science in 1989 would have enrolled in a degree in the field of education 'Information Technology' since 2001, so no perfect mapping of the current fields of education and their precursors is possible. However, by 'finessing' the figures in Tables 48 and 49 (see footnote 27 Dobson \& Calderon, 1999) and data from this century, it would seem that the proportion of a 'science/IT' degree that comprised mathematics was 17 per cent, and by 2015, it was nine per cent. Equivalent figures for the disciplines of chemistry ( 12 per cent / seven per cent), physics (seven per cent / three per cent) and biology ( 20 per cent / 23 per cent). At the same time, 'computer science / IT represented 19 per cent in 1989 and 20 per cent in 2015, but had been 33 per cent in 2002, at the height of the IT university enrolments boom. Meanwhile, 'other sciences' increased from about 10 per cent to 13 per cent, and non-sciences increased from 16 per cent to 26 per cent.

These figures have been contrived by adding enrolments in Information Technology degrees and Natural and Physical Sciences degrees, but further imperfections arise from such things as 'environmental science' students in 1989 would have enrolled in a degree in Agriculture, Environmental and Related Studies from 2001.

Concentrating again on the 21st century, there are marked differences between what men and women study in their bachelor's degree in the Natural and Physical Sciences. Although there are close-to equal numbers of men and women in these degrees, the 'average science degree' for female and male students varies, with male students being more likely to undertake subjects in Mathematical Sciences, and Physics and Astronomy, and both genders have shown a similar propensity to take subjects in the Chemical Sciences. Women are more likely to be taking subjects in Biological Sciences and Other Natural and Physical Sciences, not to mention non-STEM subjects. Men are more likely to take subjects in Information Technology and Engineering and Related Technologies. A point of interest should be that the relative uptake of Mathematical Sciences stayed the same for both women and men between 2002 and 2015, but there were small declines in Physics and Astronomy and Chemical Sciences for both genders, and also a decline in taking Biological Sciences subjects. Growth occurred in subjects in Other Natural and Physical Sciences, but the proportion represented by other STEM subjects and non-STEM subjects did not change.
Looking at domestic and overseas students, the pattern has been that there is little difference between the subjects that these two groups of students undertake. There were small changes between 2002 and 2015, with the largest change for both domestic and overseas students was a relative decline in the Biological Sciences.

An additional factor that ought to be considered when reading a volume such as this one relates to the consistency of the statistics analysed. Although Australian higher education statistics are based on a detailed data element dictionary, there is scope for the data to be reported inadequately or even incorrectly. Examples have been mentioned in the text as the came to light, such as when universities have described course completions more broadly than they should have. For example, in some places, PhD completions have been described simply as 'Natural and Physical Sciences', rather than at the Narrow Field of Education groupings such as 'Mathematical Sciences' or 'Physics and Astronomy' (etc.).

Another game changer in how one should interpret Australian university statistics has been the socalled Melbourne Model and the subsequent 'UWA Model'. Perhaps there are good reasons for adopting a version of the European Bologna system of course structures, or even the US-style graduate school model, and for their own reasons, two out of Australia's 38 universities decided it was a good idea to do so. One of the ways in which these models have the capacity to perturb university enrolment patterns a student seeking to qualify for professions such as engineering and architecture, will now
generate two commencing enrolments rather than the single enrolment to qualify in years before these models were introduced. A student who would have qualified with a BE degree after their four years' study, is now required to commence a "master's" degree before being qualified to operate as a jobbing engineer. It also seems that many students will take an extra year before they are considered job-ready and may have paid some additional fees to boot.

Related to the introduction of the Melbourne Model is the fact that many of students who formerly enrolled in a course linked to the Architecture and Building field of education started to enrol in a course classified by that university as Agriculture, Environmental and Related Studies. This has had the impact of creating an illusion that the sector is continuing to produce agricultural, environmental (and related) scientists, when this is probably not correct. The statistics show that there was no expansion overall in Agriculture, Environmental and Related Studies, but in fact, several hundred students who are likely to become architects in the fullness of time have been included in the undergraduate 'Agriculture' count.

Similarly, the requirement in most cases for future engineers (among others) at the University of Melbourne to enrol in and complete a BSc before proceeding to a putative postgraduate professional qualification in engineering (for example) means that the number of enrolments and completions in Natural and Physical Sciences bachelor's degrees has a quite different meaning than it did in the past. Several hundred BSc graduates per year will re-enrol in a different field of education, rather than seek employment as scientists, or seek enrolment in a PhD inn Science.

Does it matter if these statistical patterns have been upended? Perhaps not, but when future analysts peruse the Department's tables, they could come to the wrong conclusion.

## Appendix 1:

## Glossary of Higher Education Terms

The Glossary provides definitions of terms referred to in the text. Most of the definitions have been extracted directly from the Department's on-line user manuals.
Aboriginal and Torres Strait Islanders (See also Indigenous Students)Persons who identify themselves as being of Australian Aboriginal and Torres Strait Islander descent.

## Academic Organisational Unit (AOU)

The Department's name for what universities commonly refer to as "schools" or "departments". The concept of 'Faculty' as an aggregation of 'schools' or 'departments' does not exist in formal reporting to the Department.

## Attendance Mode

A classification of the manner in which a student is undertaking a subject:

- Internal Mode of Attendance: unit of study for which the student is enrolled and is undertaken through attendance at university on a regular basis; or
- External Mode of Attendance: unit of study for which the student is enrolled involves special arrangements whereby lesson materials, assignments, etc. are delivered to the student, and any associated attendance at the institution is of an incidental, irregular, special or voluntary nature.
- Multi-modal Mode of Attendance: a unit of study is undertaken partially on an internal mode of attendance and partially on an external mode of attendance.

## Attendance Type

Attendance is classified as being full-time or part-time, based on the student load for the student:

- Full-time: student load (EFTSL) aggregated for all the courses being undertaken by the student in the Collection Year is 0.75 or more.
- Part-time: student load (EFTSL) aggregated for all the courses being undertaken by the student in the Collection Year is less than 0.75 .

## Combined Course

A course which has been specifically designed to lead to a single combined award (eg. BSc/DipEd or $\mathrm{BSc} / \mathrm{LLB}$ ) or to meet the requirements of more than one award (e.g. BSc and BEng).

## Commencing Student

A student is a commencing student if she/he has enrolled in the course for the first time at the institution between 1 April of the year prior to the Collection Year and 31 March of the Collection Year. A Bachelor of Science student who moves into Bachelor of Science (Honours) at the same university is NOT considered to be a commencing student.

## Course

An award course, non-award course, enabling course, or cross-institution programme undertaken at a higher education institution. An award course is a programme of study formally approved/accredited by the institution or any other relevant accreditation authority and which leads to an academic award granted by the institution or which qualifies a student to enter a course at a level higher than a bachelor's degree

## Course Level

The Department's terminology is 'course type'. Course level means (for example) PhD , bachelor's degree, postgraduate diploma, etc.

## Course Completion

The successful completion of all the academic requirements of a course which includes any required attendance, assignments, examinations, assessments, dissertations, practical experience and work experience in industry.

## Discipline Group

A discipline group is a means of classifying subjects in terms of the subject matter being taught and/ or researched in them.

## EFTSL / EFTSU (Equivalent Full-time Student Load / Unit)

A measure of the student load attributable to a subject or to a set of subjects. The measure indicates the notional proportion of the workload which would be applicable to a student undertaking a full year of study in a particular year, of a particular course.

## Fee-Paying Student

A student for whom a fee is paid to the institution for tuition.

## Field Of Study / Field Of Education Classification

A classification of courses based on similarity in terms of the vocational field of specialisation or the principal subject matter of the course.

## Indigenous Students

Persons who identify themselves as being of Australian Aboriginal and Torres Strait Islander descent.

## Overseas Student

A student who is NOT one of the following:

- an Australian citizen; or
- a New Zealand citizen, or a diplomatic or consular representative of New Zealand, a member of the staff of such a representative or the spouse or dependent relative of such a representative; or
- a person entitled to stay in Australia, or to enter and stay in Australia, without any limitation as to time and resides in Australia during the semester.

Student Load See EFTSL/ EFTSU.

## Subject

The basic component of a course or programme, which a student may undertake and on successful completion of the unit's requirements, gain credit towards completion of the course. In this study, the term has been used interchangeably with 'unit'.

UNIT See 'Subject'

[^1]:    4 Until the so-called Dawkins reforms of the late 1980s / early 1990s, Australia had research-oriented universities and teachingoriented institutions known as colleges of advanced education or institutes of technology. Among Dawkins' reforms was the creation of a unitary system (of universities), effected by a mixture of mergers/takeovers and institutional redesignations.

    11 In brief, the terminology adopted here is that a 'course' is a study programme, such as $\mathrm{BSc}, \mathrm{BA}, \mathrm{MBA}$ or PhD . The components of courses are 'subjects'. For instance, a first-year student enrolled in a BSc degree might be taking Mathematics 1, Chemistry 1, Physics 1 and Biology A. Some courses, such as PhD may not have any classroom component, and therefore may not be comprised of subjects as such. It is also the case that some students enrol in more than one course.
